

## JAVA

Date: / /

Keywords are case sensitive: public, Public, PUBLIC are all different

Keywords

```
public class Hello { } //part /body
```

} code block

public - optional access modifier.

Method: It is a collection of statements (one or more) that performs an operation.

Main method - entry point of any java code. Java looks for it when running any program

```
public class Hello { }
```

```
public static void main (String args[]) { }
```

S.O.P ("Hello"); → Statement

} code block

}

}

Statement: a complete command to be executed and can include one or more expressions

Variables: a way to store information in our PC.

- can be changed, variable content
- stored in RAM

To define a variable we need to specify data type, then give its name and optionally add an expression to initialize it with a value

int mynumber = 5; → Declaration statement.

↓  
data type, name, optional set value

Expression: it is a construct that evaluates to a single value

Primitive Data Types - Total 8

int byte short float  
boolean char long double

int → min & max value

Integer.MIN-VALUE, Integer.MAX-VALUE  
wrapper class.

Java uses the concept of wrapper class for all 8 primitive types.

int - min -2147483648

max 2147483647

\* Note: If you try to put a larger than max value, or smaller than min value, then you will get an overflow in case of max &

underflow in case of min.

The computer skips back to min or max number.

eg:

$$\text{int } i = 2147483647 + 1 \Rightarrow \text{O/P} -2147483648$$

$$\text{int } i = -2147483648 - 1 \Rightarrow \text{O/P} 2147483647$$

\* int maxInt =  $-2^{147-483-647}$ .

(can be written this way in Java 7 or higher to make it readable)

Byte - Byte.MIN-VALUE = -128 Max = +127.

small in size might help in performance but today PC's have a lot of space so no need to worry about it.

Short -32768 to 32767

Width

Byte : 8 bits  $\Rightarrow 2^7$

Short 16 bits  $\Rightarrow 2^{15}$

int 32 bits  $\Rightarrow 2^{31}$

long 64 bits  $\Rightarrow 2^{63}$

long :

long mylongvalue = 100L;  $\Rightarrow$  L represents it is a long value (uppercase)

By default, java takes number as int. So this L is needed in case of long numbers.

## Casting

(x)

byte mybyte = (myMinByteValue/2);

int default in java is int

=> (byte)(myMinByteValue/2)  
↑  
casting.

float - single precision no.  $\rightarrow$  32 bits  $\Rightarrow$  width=32

double - double precision no  $\Rightarrow$  64 bits  $\Rightarrow$  width=64

Precision = format & amount of space occupied by the type.

\*

double is default type for real no's

\*

int is ——— whole no's.

float myfloat = 5f; 5.25 x error float(5.25)

double mydouble = 5.25d;

char - can store a single character

— occupied 2 bytes = 16 bits. (bcz it allows to store unicode chars all)

Unicode - international coding standard

char myunicode = '\u00d4';

unicode 'D'  $\rightarrow$  unicode table mein se 00d4 4ya

Boolean  $\rightarrow$  True or False

String → it is a class, easy to operate

→ immutable (cannot be deleted once created)

→ string + any datatype  $\Rightarrow$  string.

**Operator** - Special symbols that perform specific operations.

**Operand**: object manipulated by operator.

**Expression**: is formed by combining variables, literals, method return values and operators.

- logical and  $\rightarrow \&&$

- logical OR  $\rightarrow \|\|$

- NOT  $\rightarrow !$

-  $\&, | \rightarrow$  bitwise operator

- Ternary

boolean isCar = false;

boolean wasCar = isCar ? true : false .

Statement

int [rryint = 50];

expression

Method Overloading - a feature that allows us to have more than one method with same name, so long as we use different parameters.

e.g.: `println`.

→ improves readability, re-usability

→ easy to remember one method name instead of multiple

Changing return type does not include in method overloading

```
int sum(int a, int b)  
float sum(int a, int b) → will give error.
```

→ change no. of parameters

→ datatype of parameters

→ changing sequence (`int, double`) - (`double, int`)

### switch

can be used with byte, short, int or char, strings.

```
switch(var)
```

```
{
```

```
case 1: break;
```

```
case 2: break;
```

```
default: break;
```

```
}
```

~ \* Switch ('January')

```
{
```

```
case january: break
```

```
default: work;
```

// will go to default

case should be same

Java has 50 keywords.

Date: / /

a. tolowercase().

autouppercase();

\* for

\* while (condition) {

}

\* do

{

→ execute atleast once

} while (condition);

\* int cnt = 1 → initialize

while (cnt <= 5) { → condition

cnt++ → increment.

3. control statements

init cond in  
for (int i=1; i<=5; i++)

some keywords

\* continue

\* break

3

do {

cnt++ → sine.

} while (condition);

} → cond

→ convert String into int

String str = "2018"

~~str.~~int n = Integer.parseInt(str);  
/Op 2018

String str = "2018a"

int n = Integer.parseInt(str) // error since 2018a is not an int

→ Double.parseDouble

→ Float.parseFloat

### Scanner

Scanner scanner = new Scanner(System.in);

System.in → allows to type input in console which gets returned back to the program

new → used to create instance of class Scanner / create object

Name = scanner.nextLine();

scanner.close(); // to release memory Scanner was using.

scanner.nextInt();

scanner.nextLine(); → Handles enter key issue

- when you press enter after taking int  
it takes it as break, so ends there hence use nextLine();

IMP \*

int yearBirth

scop("Enter year");

boolean hasNextInt = sc.hasNextInt(); // returns if no is int.  
yearBirth = sc.nextInt();

### classes

this.model = model → local var. of method  
var. of the class.

Constructors - can be overloaded

- always public.

- you can call one constructor in other.

- this(), should always be first line in the constructor  
one calling other constructor inside it.

eg:-

public class Car {

public Car() {

scop("empty");

}

→ car1, "Volvo");

public Car(int model, String name)

{

this();

O/P - empty

this.model = model;

not empty

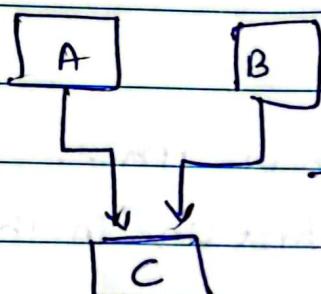

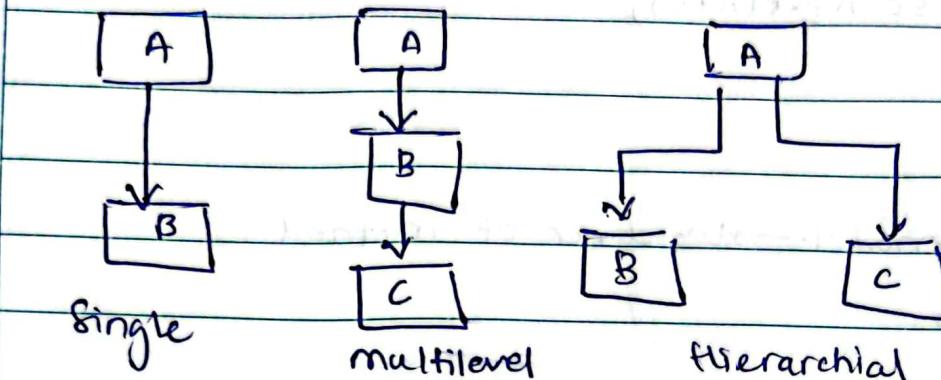

this.name = name;  
scop("not empty");

}

## Inheritance

→ extends

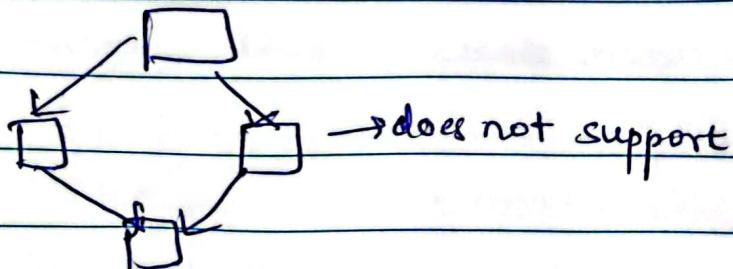

→ super();

multiple

→ Java does not support

It can be achieved only through interfaces

Reference vs Object vs Instance vs Class.

Consider building a house

Class: - blueprint for a house, we can build as many houses as we like with that blueprint/plan

Instance: Each house you built, is an object/instance.

Reference: Each house has an address, ie-a reference

You can copy the reference as many times as u like but there is still one house

We can pass references as parameters to constructors & methods

eg: class House{

    public class Main {

        put String color;

    ① House blueHouse = new House("blue")

    public House (str color)

    ②. House anotherHouse = blueHouse;

    } this.color = color; }

    ③ System.out.println(blueHouse.getColor()); //blue

blueHouse anotherHouse

    ④ System.out.println(anotherHouse.getColor()); //blue

    ⑤ anotherHouse.setColor("red");

    ⑥ System.out.println(blueHouse..); //red  
    ⑦ System.out.println(---); //red.

③ blueHouse anotherHouse,

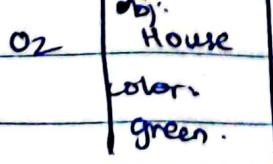

④ House greenHouse = new House("green")

⑤ anotherHouse = greenHouse;

System.out.println(greenHouse.getColor()); //green

System.out.println(anotherHouse.getColor()); //green.

GreenHouse.

## this vs super

super() is used to access/all parent class members  
→ commonly used with method overriding

this → used to call current class members. This is required when we have a parameter with same name as an instance variable.

Note: We can use both anywhere except in static areas (the static block or static methods). Any attempt at this will give compile time errors.

this() → only used in constructor to call another overloaded constructor.

→ this(); should be first statement in a constructor.

super() → Java by default calls it if we don't

→ call to super() must be first statement in the constructor

A constructor can call super(); or this() but not both

Constructor example:

class Rectangle {

    int x;

    int y;

    int width;

    int height;

Constructor  
Chaining

The last constructor has  
responsibility to initialize the  
variables.

public Rectangle {

    this(0, 0);

}

public Rectangle(int width, int height)

{

    this(0, 0, width, height);

}

public Rectangle(int x, int y, int width, int height)

{

    this.x = x;

    this.y = y;

    this.width = width;

    this.height = height;

}

actual initialization is  
happening here

## Overloading vs Overriding

Overloading - same name, diff parameters

- return type may or may not be different

### Compile time Polymorphism

- we can overload static & instance methods

- usually overloading happens inside a single class, but a method can be treated overloaded in subclasses of that class

## Overriding

- Runtime Polymorphism

- defining a method in child class that already exists in parent class with same signature (name, args)

### @Override - annotations

- you can't override static methods

- It can't have a lower access modifier → <sup>parent</sup> private & <sup>child</sup> protected ~~X error~~

- only inherited methods can be overridden.

- constructors & private methods can't be overridden.

- final methods can't be overridden

- is-a relationship, therefore we can overwrite

## \* Covariant return type \*

### Static methods

- are declared using static modifier
- can't access instance methods & instance variables directly.
- usually used for operations that do not require any data from an instance of class (from 'this').
- we can't use 'this' keyword in static.
- does not require object to access it  
classname.methodname()

### Instance methods

- belong to an instance of a class
- to use it you have to instantiate the class first by using new keyword
- can access instance methods & var. directly
- can access static —||—

#### Static var

- declared by using static keyword

- aka static ~~instance~~ member variables

- every instance of class shares same

static variable

- one change is reflected in all

instances

#### Instance var

- belongs to instance of a class

- represent state of specific

instance

Inheritance - Is-A

Vehicle → Car. Car is a vehicle.

Composition has-A

Computer → Keyboard. PC has a keyboard.

eg. - Main.java - In main create bedroom

Bedroom.java - Bedroom has wall, lamp etc.

wall.java

lamp.java

## Implementation methods

- Math.round() → returns long

Method Function

leapyear-

if (year % 4 == 0)

{ if (year % 100 == 0)

{ if (year % 400 == 0)  
return true;

else return false;

return true;

{

else return false;

- String.toLowerCase(), String.toUpperCase()

- Math.sqrt(n) → long

Diagonal star.

.equals("y")

Arrays.toString(arr)

String.equals(str2)

String.compareTo(str2)

&gt;0 Equal

&gt;0 S2 &gt; S1

=0 S1 = S2

- cities.isEmpty() → checks if null string.

default - int - 0  
boolean - false

Date: / /

String - null.

### Arrays:-

int[] array = new int[10];  
array[5] = 50;

double[] arr = new double[10];

### Declaration

(1) dataType[] arr; (2) dataType []arr (3) dataType arr[];

### Instantiation.

arrayRefVar = new dataType[size];

### Initialize

arrayRefVar[n] = 10;  
arrayRefVar[5] = 11;  
arrayRefVar[8] = 12;

arr.length → length of array.

int[] arr = {33, 34, 35}.

### for-each loop.

```
for (datatype variable : array)  
{  
    ---  
}
```

```
for (int i : arr)
```

```
{
```

```
    sop(i);
```

```
}
```

2-D array:

## Declaration

- `datatype[] [] arrRefVar;`
- `datatype [][] arrRefVar;`
- `datatype arrRefVar[][];`
- ~~`datatype @] arrRefVar[];`~~

```
int arr[][] = {{1, 2, 3}, {4, 5, 6}, {7, 8, 9}};
```

Jagged array - array of arrays with diff. no. of columns.

```
int arr[][] = new int[3][];
```

```
arr[0] = new int[3];
```

```
arr[1] ——— [4];
```

```
arr[2] ——— [2];
```

diff no. of columns.

## Section 8: Arrays, inbuilt lists, Autoboxing & Unboxing

Initialization:

```
int[] myArray = new int[10];
```

```
int[] myArray = {1, 2, 3, 4, 5, 6, 7, 8, 9};
```

valid only when arr is first declared

→ .length → returns length of the array.

```
myArr.length
```

Declaration.

Instantiation

```
datatype[] arr;           arrayrefVar = new datatype[size];
datatype []arr;
datatype arr[];
```

for-each

```
for (datatype Variable : array)
```

```
{
```

```
...
```

```
}
```

```
for (int i : arr)
```

```
{
```

```
SOP(arr[i]);
```

```
}
```

2D array.

Declaration

```
datatype[][] arrrefvar;
datatype [][] arrrefvar;
datatype arrRefvar[][];
datatype [][] arrrefvar();
```

```
int arr[][] = {{1, 2, 3}, {4, 5, 6}};
```

Jagged array: array of arrays with diff. no. of columns

```
int arr[][] = new int[3][];
```

```
arr[0] = new int[3];
```

```
arr[1] = new int[4];
```

```
arr[2] = new int[2];
```

## Reference Type vs Value Types.

```
int n1 = 10
```

```
int n2 = n1;
```

```
SOP(n1) // 10
```

```
SOP(n2) // 10
```

```
n2++;
```

```
SOP(n1) // 10
```

```
SOP(n2) // 11
```

# Both variables work independently.

Reference types work differently.

```
int[] arr1 = new int[5];
```

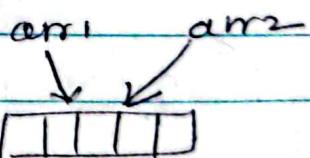

```
int[] arr2 = arr1;
```

```
SOP(arr1);
```

// 0 0 0 0 0

```
SOP(arr2);
```

// 0 0 0 0 0

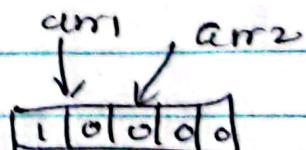

```
arr2[0] = 1;
```

```
SOP(arr1);
```

// 1 0 0 0 0

```
SOP(arr2);
```

// 1 0 0 0 0

```
modifyArray(int array)
```

```
{ array[0] = 2;
```

```
array = new int[] {1, 2, 3, 4, 5};
```

modifyarray(arr2);

SOP(arr1); // 2, 0, 0, 0, 0

SOP(arr2); // 2, 0, 0, 0, 0

arr2 = new int[] { 4, 5, 6, 7, 8 };

modifyarray(arr1);

SOP(arr1); // 2 0 0 0 0

SOP(arr2); // 4 5 6 7 8

## Strings

- backed internally by char array.
- since arrays are immutable, so are strings.
- whenever a change in string is made, an entirely new string is created.

String str = "aeeku"; — literal, stores in oury or string constant pool

or

String str = new String("aeeku"); — dynamically allotted

Stones in heap, need to internalize to store in JVM.

1) String class: (writing points. Ques = 3 writing points)

2) StringBuffer (05) — → = 2 writing points

3) StringBuilder. (writing) — →

### 1) String class

- sequence of characters.

- 2 ways to initialize as above.

methods:

- int length()

- char charAt(int i)

- String substring(int i) → substr from index i to end

- String substring(int i, int j) → i to j-1. (just explain)

- String concat(String str) → concatenation. (just explain)

- int indexOf(String s) → index of first occurrence of s.

- int indexof(String s, int i) → index count from i.

- int lastIndexOf(String s). - last occurrence. to understand this

- boolean equals(Object o) O1.equals(o2) (just explain)

- boolean equalsIgnoreCase(String s)

- int compareTo(String s2)       $s_1 < s_2 \leftarrow 0$        $s_1$  comes before  $s_2$

$s_1 = s_2 \leftarrow 0$

- compareToIgnoreCase()       $s_1 > s_2 \leftarrow 0$        $s_1$  comes after  $s_2$ .

String tolowercase()

String touppercase()

String trim()

String replace (char old, char new)

## 2) String Buffer

- mutable. (growable & writable char seq).

- extends from object class.

- safe for multiple threads, can be synchronized when needed

StringBuffer s = new StringBuffer(); // leaves room for 16 chars

StringBuffer s = ————— (20) // 20 chars

————— 16 ————— ("Geeks")

### methods -

- append()

- length()

- capacity()

- charAt()

- delete()

deleteCharAt()

ensureCapacity() .

insert() → at specified index.

reverse()

replace()

- all methods of string class .

- toString()

### 3) StringBuilder :

- mutable.
  - does not guarantee synchronization.
  - faster than StringBuffer.
  - not safe for multiple threads.

```
StringBuider str = new StringBuider("hi");
```

( )

(20): 1/capacity = 20

Methods - all as Buffer one.

## List and ArrayList

(More on lists later)

ArrayList → a resizable list

```
private ArrayList<String> grocerylist = new ArrayList<String>();
```

grocerylist  
↓  
datatype/  
object etc.  
name of var

We have this bcoz  
ArrayList is a class.  
So this is a call to  
empty constructor.

- grocerylist.add(item); // to add an element to the list
- grocerylist.size() // how many elements in that list
- grocerylist.get(i) // get element at i<sup>th</sup> index of the list  
// starts from 0
- grocerylist.set(position, newItem);  
    ↓           ↓  
    index       new value to be stored at the index.
- grocerylist.remove(position)  
    ↓  
    index.
- grocerylist.contains(searchItem);  
// returns T or F if the list has the item or not
- grocerylist.indexOf(searchItem)  
// returns index of item to be searched or -1 if not found

//copy one arraylist to other

① ArrayList<String> newArray = new ArrayList<String>();  
newArray. addAll(grocerylist. getGrocerylist());  
getter.

② ArrayList<String> newArray = new ArrayList<String>(  
grocerylist. getGrocerylist());

③ //convert to array

String[] myArray = new String[grocerylist. getGrocerylist().size()];  
size of the actual list

myArray = grocerylist. getGrocerylist(). toArray(myArray);

## Autoboxing and Unboxing

We cannot do something like

```
ArrayList<int> intArrayList = new ArrayList<int>();
```

(X) Error

int is a primitive type. It is not a class.

What to do?

→ Create a class

```
class IntClass {
```

```
    private int myValue;
```

// constructor, getter, setter

```
    }
```

```
ArrayList<IntClass> intArrayList = new ArrayList<IntClass>();
```

```
intArrayList.add(new IntClass(5));
```

→ Integer class

```
ArrayList<Integer> newList = new ArrayList<Integer>();
```

```
for (i=0; i<10; i++)
```

```
{
```

```
    newList.add(Integer.valueOf(i)); → Autoboxing
```

```
}
```

```
SOP(newList.get(i).intValue()); → Unboxing
```

[valueOf()]

→ But u don't need to do this, java provides easy way

```
Integer myIntVal = 5;
```

```
int myInt = myIntVal;
```

// Use double if its a double etc

## Linked List:

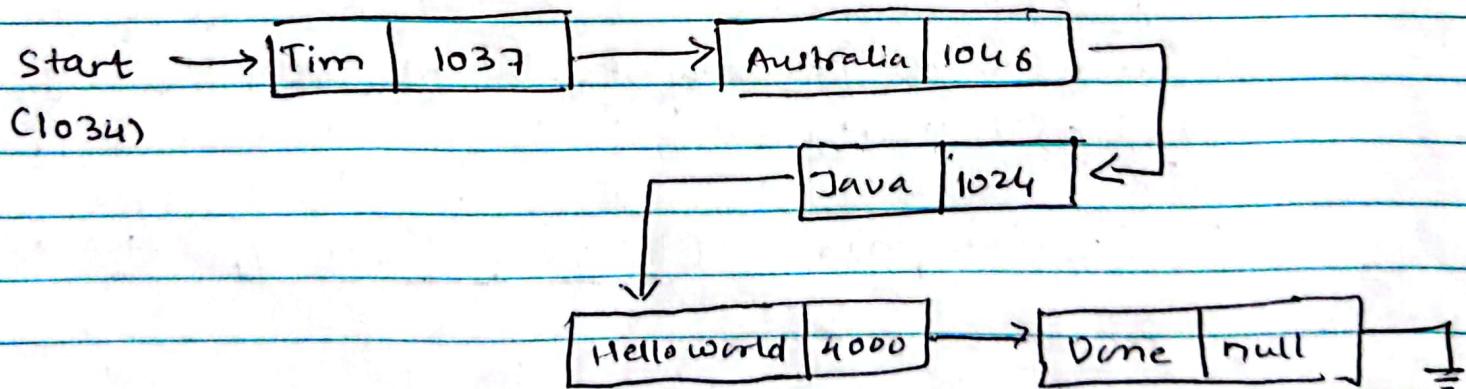

Index	Address	Value	
0	100	34	
1	104	18	<u>base index + (index - 1) * 4</u>
2	108	91	
3	112	57	
4	116	453	

for strings.

Index	Addr.	Str. Addr	
0	100	1034	1024 - HelloWorld
1	108	1037	1034 - Tim
2	116	1046	1037 - Australia
3	124	1024	1046 - Java
4	132	4000	4000 - Done.

linked list → stores link to next item in the list

→ also stores actual data

\* If u want to add new rec, u just need to change two pointers

```
import java.util.LinkedList;
LinkedList<String> placesToVisit = new LinkedList<String>();
placesToVisit.add("A");
--> ("B");
```

// printing

\* Iterator<String> i = placesToVisit.iterator();

while(i.hasNext())  
{

sop (i.next());

3. outputting 'or' of elements of list or

t → placesToVisit.add(1, "C"); // index=1, value=c

print.

// A

C

B.

// Remove.

placesToVisit.remove(i); // index.

\* List iterator

\* ListIterator<String> itr = linkedList.listIterator();

while(itr.hasNext())  
{

int compare = itr.next().compareTo(newCity);

if(compare == 0)

↳ // same city exists

3

else if(compare > 0) // to be added before

{

itr.previous();

itr.add(newCity)

3

else if (compare ==)

{

// just move to next

}

itr.add(newCity); // reached end of list

3.

\* The iterator is not pointing to first entry.

You need to use .next() to go to first entry

.next() → returns next element in the list & advances cursor pos

\* Java implements linkedlist as double linked list

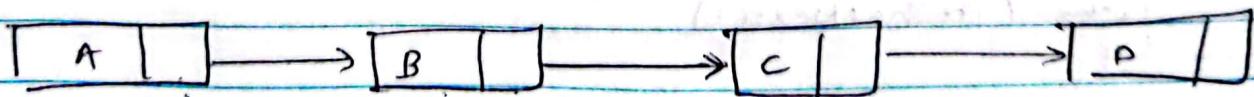

Problem with next, prev.

A → B → C → D → E → F

case1 → forward

case2 → backward

A → B → C → (C) → ? Problem.  
① → ②

↑ pointing to c next if going forward.  
so if I do previous, it points to B

But I want it to point to A.

So I need to do prev, if going forward

& forward, if going backwards.

boolean goingforward = true;

case 1: go to next city

```
.if (!goingforward) {  
    if (listIterator.hasNext())  
        {  
            listIterator.next();  
        }  
    }  
    goingforward = true;
```

Vilage ja raha hai to  
goingforward should be  
Set to true.

g. extra .next

```
if (listIterator.hasNext())
```

```
{
```

```
sop ( now visiting + listIterator.next());
```

```
}
```

```
else {
```

```
sop ( At the end of list).
```

```
}
```

case 2: go to prev city.

```
if (goingforward)  
{
```

```
    if (listIterator.hasPrevious())
```

```
{
```

```
        listIterator.previous();
```

```
}
```

```
        goingforward = false;
```

```
}
```

```
    if (listIterator.hasPrevious())
```

```
{
```

```
        sop ( now visiting + listIterator.previous())
```

```
}
```

```
else
```

```
sop ( At the start of list)
```

Peeche - goingforward → false  
extra .previous()

Set: unordered collection with no duplicates.

- it is an interface.

- insertion order is not retained.

Set<obj> set = new HashSet<obj>();

Methods -

- add()

operations  
Union

- addAll()

Set a, set b.

- clear() → remove all

a.addAll(b).

- contains(element)

- Intersection.

- containsAll(collection)

b.addAll(a)

- hashCode()

OR a.addAll(b)

- isEmpty()

- iterator()

- remove(element)

- size()

- toArray()

## Operations

Set a, set b

Set union // contains a

union.addAll(b);

Set<integer> intersection = new HashSet<>(a);

intersection.addAll(b);

Set<integer> difference = new HashSet<>(a);

difference.removeAll(b);

Abstraction - display only essential details shape  
*begin, don't know  
you don't know  
how it works*

- interface & abstract classes
- implementation hiding

Encapsulation - wrapping up data under a single unit.

Hashtable

- access modifiers (private var, public methods)
- data hiding getter, setter
- restricting access to methods & attributes, prevent data being modified by accident

Inheritance: - reusability

Polymorphism: 1) Overload - 3 types.

2) Override.

Interface - 100% abstraction.

only abstract methods  
only static and final var.  
method - public abstract  
var → public static final.  
implements.

can extend other interface only

- public members.

super - access parent class var/method

final - applicable to var, method, class.

var - constant var

method - prevents overriding

class - prevent inheritance (String class)

Abstract class

abstract/non abstract methods  
can have final/non final,  
static/non static.  
extends.

can extend interfaces &

other classes:

- public/protected

cannot be used to create obj;  
must be inherited.

Static: share var/method

static block - to init static var, runs only once when class is first loaded

static methods - main(), used without creating object to occur

## Q8 - Linked List - Insert / Delete.

```

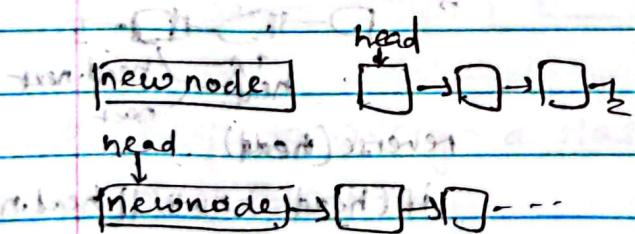

class Node {
    int data;
    Node next;
    Node(int d) {
        data = d;
        next = null;
    }
    void print() {
        System.out.print(data + " ");
        if (next != null)
            next.print();
    }
}

class Main {
    static Node head;
    public static void main(String[] args) {
        head = new Node(1);
        head.next = new Node(2);
        head.next.next = new Node(3);
        head.next.next.next = new Node(4);
        head.print();
    }
}

```

### Insert:

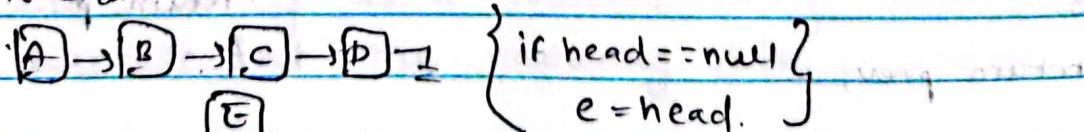

- 1) At front

① newnode.next = head;

② head = newnode;

- ③ At end.

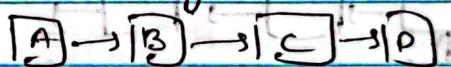

e.next = null;

as to D

D.next = e;

- 2) After a given node. (B)

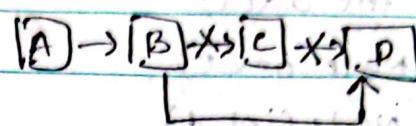

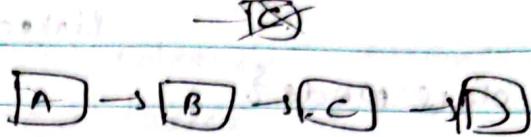

e.next = b.next;

b.next = e;

## Delete

- 1) Find previous
2. change next of prev
- 3) free memory of node to delete

```
delete(node n, head)
{
```

curr = head;

while(head->next!=n)

{ head = head->next

}

```
delete (node n, head)
{
```

curr = head;

if(head!=null & head.val=c)

{ head=null;

return head;

}

while(curr.next!=n)

curr = curr.next;

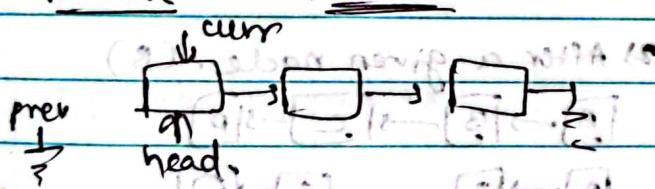

curr.next = n.next;

n.next = null;

free(n)

## Reverse

### Iterative

while(curr!=null)

{

next = curr.next;

curr.next = prev;

prev = curr;

curr = next;

}

return prev;

### Recursive

- go till end.

→ D -> E -> F -> G -> null.

next

last to null

head

next

reverse(head)

. if(head==null || head.next==null)

return head;

listnode p = reverseList(head.next)

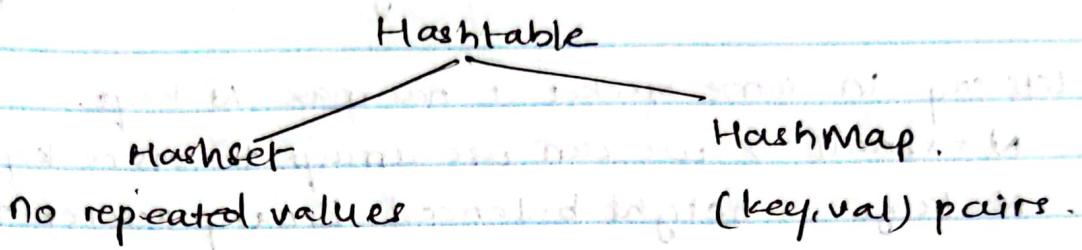

head.next.next = head

head.next = null

return p.

Hashtable - hashmap, hashset.

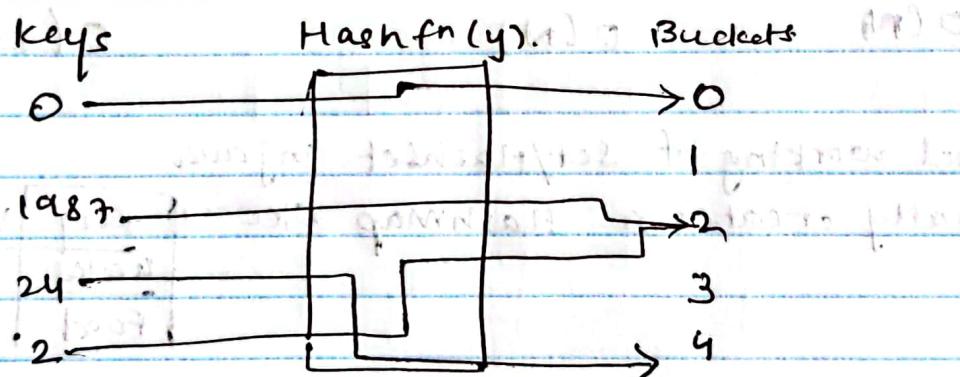

Hashtable: is a data structure which organizes data using hash functions in order to support quick insertion and search.

## \* Principle of Hash Table

→ use a hash function to map keys to buckets.

e.g. hash fn g =  $x \% 5$

## \* Keys to Design a Hash Table

## 1. Hash Function.

Hash fn will depend on the range of key values and the number of buckets.

- The idea is to assign a key to bucket as uniformly as possible
    - ideal hash fn → 1-1 mapping b/w key & bucket.
  - but usually it's a tradeoff b/w the amount of buckets and the capacity of a bucket

## Q. Collision Resolution -

1. How to organize values in same bucket?

what if too many values in same bucket?

3. How to search for a target value in a specific bucket?

lets say, in some bucket it has max  $N$  keys.

$N = \text{small} \Rightarrow$  we can use arrays to store keys in same bucket

$N = \text{large} \Rightarrow$  height balanced binary search tree

$N = \text{max bucket size}$

insert

Array  
 $O(1)$

Hashtable (LL)  
 $O(1)$

Hashtable (BST)  
 $O(1)$

search

$O(M)$

$O(N)$

$O(\log N)$

Internal working of Set/HashSet in java

→ Internally creates a HashMap like

key	val
Object	Present
Food	Present

so when u call add method of HashSet it internally calls put method of HashMap.

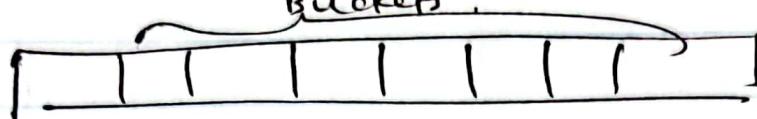

with object u specified as key and 'Present' as its value.

if (map.put(key, "present") == null, then add to HashSet  
true internally HashMap

If ( ————— ) != null and hence not added.  
false:

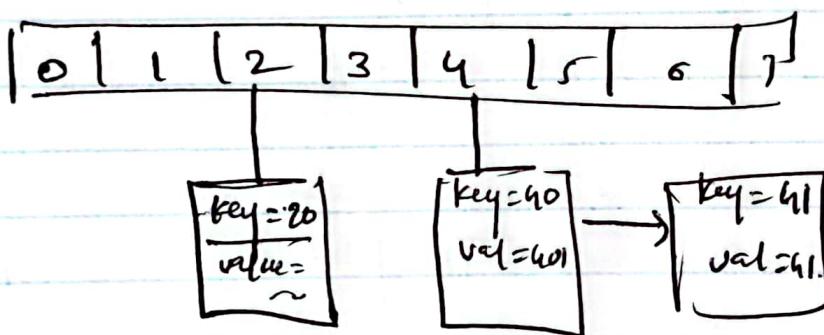

## Internal working of HashMap in java.

- calculate hashCode() using the hash fn.
- uses equals() method to compare keys.
- Buckets → one element of Hashmap array

while insertion / -

- If no collision add to that bucket
- If key is same, update value
- If key is not same, add another node' in the list

Java HashSet

add()  
clear()  
clone()  
contains()  
isEmpty()

iterator  
remove(object),  
size(),

HashMap

put()  
clear()  
containsKey()  
containsValue()  
entrySet()  
get(),  
keySet(),  
putAll()  
remove(),  
remove(key, val)  
remove(K, V),

## Search Algorithm

### Linear Search

```
linearsearch(-15) {  
    arr = {20, 35, -15, 7, 55, 1, -22};  
    ↑ ↑ ↑  
    x x yes -
```

```
for (i=0; i<arr.length; i++)
```

```
{
```

```
if (arr[i] == -15)
```

```
return true.
```

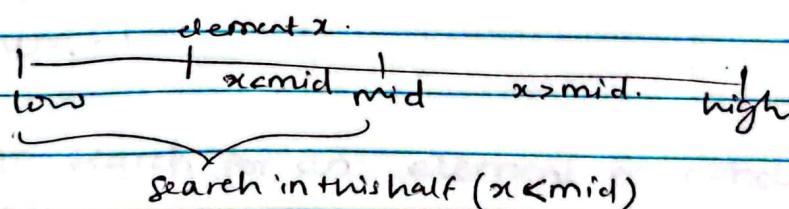

```
}
```

```
return false.
```

→  $O(n)$

### Binary Search

- Data must be sorted.

chooses element in middle of array & compares it against the search value.

1)  $low = 0$ ,  $high = arr.length - 1$ ,  $mid = (low + high) / 2$ .

```
while (low <= high)
```

```
{
```

```
    mid = (low + high) / 2;
```

```
    if (x == arr[mid]) return 1;
```

```
    else if (x < arr[mid])
```

```
        high = mid - 1;
```

```
    else low = mid + 1;
```

```
}
```

```
return 0;
```

## 2) Recursive

```
binsearch (arr[], x, low, high)
{
    mid = (high + low) / 2
    if (low > high) return 0; //not found
    if (x > arr[mid]) return binsearch (arr, x, mid+1, high)
    else if (x < arr[mid]) return -1 — binsearch (arr, x, low, mid-1),
    else return 1 //found.
```

}

→  $O(\log n)$

Space —  $O(1)$ . for iterative algorithm.

## Binary search

Overflow problem:  $m = (l+r)/2$  - can overflow in java  
so use  $m = l + (r-l)/2$  instead.

### Template I

```
int binarysearch(int[] nums, target)
{
```

```
    if (nums == null || nums.length == 0)
```

```
        return -1
```

```
    int l = 0, r = nums.length - 1;
```

```
    while (l <= r)
```

```
    {
```

```
        m = (l + (r - l)) / 2;
```

```
        if (nums[m] == target) return mid;
```

```
        else if (nums[m] < target) l = m + 1;
```

```
        else r = mid - 1;
```

```
}
```

```
    return -1
```

3.

Used to search for an element or condition which can be determined by accessing a single index in the array.

### Template II

Used to search for an element or condition which requires accessing the current index & its immediate right neighbour's index in the array.

Used when requires accessing current index and its immediate left and right neighbours index in the array.

### Template - II

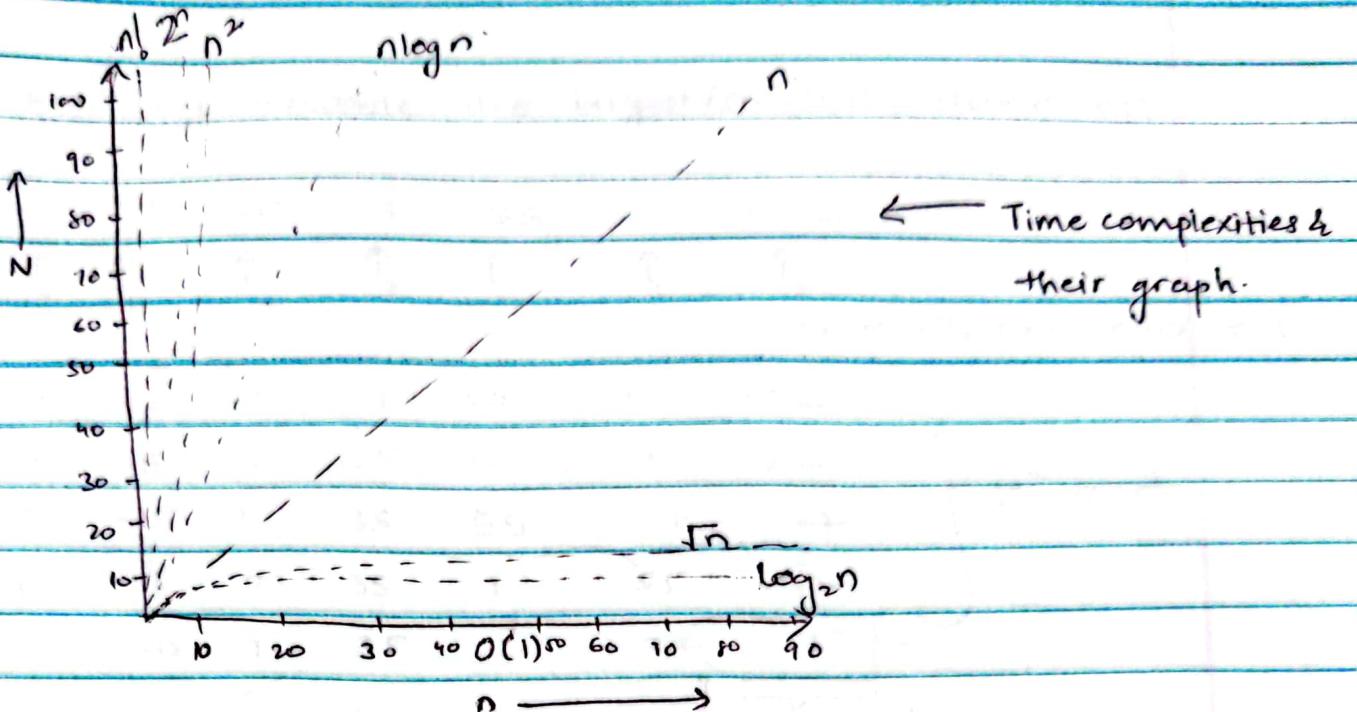

```
int binsearch( int[] nums, int target)
{
    if( nums == null || nums.length == 0 )
        return -1;
    int l = 0, r = nums.length;
    while( l < r )
    {
        int mid = l + (r-1)/2;
        if( nums[mid] == target ) return mid;
        else if( nums[mid] < target ) left = mid+1;
        else right = mid;
    }
    if( left == nums.length && nums[left] == target ) return left;
    return -1;
}
```

### Template - III

```
int binsearch( )
```

```

if( nums == null || nums.length == 0 )
    return -1;
int l = 0, r = nums.length-1;
while( l+1 < r )
{
    mid = l + (r-1)/2;
    if( nums[mid] == target )
        return mid;
    else if( nums[mid] < target ) l = mid;
    else r = mid;
}
if( nums[l] == target ) return l;
return -1;
```

$$n^6 > 2^n > n^2 > n \log n > n > \sqrt{n} > \log n = o(1)$$

*Argiope* *diademata* *quadrifasciata*

Bubble Sort: - bubble the largest/smallest value to end

20 35 -15 7 55 1 -22  
↑ ↑ ↑ ↑ ↑ ↑ ↑ ↑  
(from n to 1) unsorted PartitionIndex = 6.

20 -15 35 7 55 1 -22

20 -15 7 35 55 1 -22

20 -15 7 35 55 1 -22

20 -15 7 35 1 55 -22

20 -15 7 35 1 -22 [55] -

unsorted.

sorted

unsorted PartitionIndex = 5.

-15	20	7	20	1	-22	[35   55]
-15	7	1	-22	[20   35   55]		
-15	1	-22	[7   20   35   55]			
-15	-22	[1   7   20   35   55]				
-22	-15	1	7	20	35	55

→  $O(n^2)$  → Worst Best -  $O(n)$ . Arg:  $O(n^2)$ . space: -  $O(1)$  auxillary.

```
for (int lastUnsortedIndex = arr.length - 1; lastUnsortedIndex > 0; lastUnsortedIndex--)
```

```
    for (int i = 0; i < lastUnsortedIndex; i++)
```

```
        if (arr[i] > arr[i + 1])
```

```
            {  
                int temp = arr[i];  
                arr[i] = arr[i + 1];  
                arr[i + 1] = temp;  
            }
```

3

→ only advantage it can detect if p is already sorted or not.

OR

```
for (int i=0; i<arr.length; i++) → Run total element - 1 time
{
```

```
  for (int j=0; j<arr.length-i-1; j++) → arr is sorted from end
  {
```

so no need to check  
till end.

```
  if (arr[j] > arr[j+1])
```

```
    { swap
```

```
    {
```

```
    }
```

```
    }
```

```
  }
```

```
}
```

```
loop
```

```
break
```

Stable vs Unstable sort

- when u have duplicate values

```
5 9 3 2 9 8 4 → arr.
```

duplicates

- if original ordering is preserved → stable

- if not → unstable

- stable preferred (consider string name, age, one sort in other)

Bubble → Stable.

if (arr[i] > arr[i+1]) → complexity  $O(n)$ .

{ swap

swapped = 1

{

3

Selection sort → Repeatedly selects smallest element

- find min. in the list

- swap with value in current pos.

- Repeat until all array is sorted

```
for (i=0; i < arr.length-1; i++)
```

```
{ min = i;
```

```
    for (j=i+1; j < arr.length; j++)
```

```
{
```

```
    if (A[j] < A[min])
```

```
        min = j
```

```
}
```

// Swap

temp = A[min]

A[min] = A[i]

A[i] = temp.

Worst case -  $O(n^2)$

Best -  $O(n^2)$

Avg -  $O(n^2)$

Space -  $O(1)$

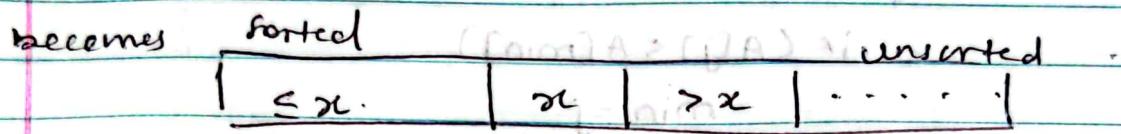

Inversion sort - inserts the element into correct position in already sorted list until no input elements remain.

The resulting array after k iterations has property that  $k+1$  entries are sorted.

Sorted partial  
reg.

Unsorted elements

for (int i = 1, i < arr.length; i++)

{

    int j;

    int partition = arr[i];

    j = i;

    while (j >= 1 && arr[j-1] > partition)

    {

        arr[j] = arr[j-1]

        j--;

}

    arr[j] = partition;

}

Note: IMP

{ this should be first condition to check else j-1 goes +1 & we get index out of bound when j=0 }

\* Practically more efficient than selection & bubble, even when it is O(n<sup>2</sup>)

- Stable

eg -

6 8 1 4 5 3 7 2.

16 8 1 4 5 3 7 2.

6 8 4 5 3 7 2.

1 4 6 8 5 3 7 2.

1 4 5 6 8 3 7 2.

1 3 4 5 6 7 8 2. - missing iteration.

1 2 3 4 5 6 7 8.

Worst case - when all elements have to move right.

$$T(n) = O(1) + 4 O(2) + \dots + O(n-1)$$

$$\approx O(n^2).$$

Worst -  $O(n^2)$

Best -  $O(n)$

Avg -  $O(n^2)$ .

Space -  $O(n^2)$  total,  $O(1)$  auxiliary.

- used when data is nearly sorted due to its adaptiveness or i/p is small.

Bubble.

comparision

$$\frac{n^2}{2}$$

Inversion/swap

$$\frac{n^2}{2}$$

selection

$$\frac{n^2}{2}$$

$$n \cdot 1$$

Insertion

$$\frac{n^2}{4}$$

$$\frac{n^2}{8}$$

- Insertion sort is almost linear for partially sorted list.
- Selection sort is best suit for elements with bigger values & small keys.

### Shell sort:

- variation of insertion sort.
- Insertion sort chooses the element using gap = 1.
- Shell sort uses larger gap.
- Goal → reduce amt. of shifting reqd
- last gap value is always 1.
- So, shell sort does some preliminary work (using gap values > 1) & then becomes ins. sort. By the time it does ins. sort, elements are partially sorted. ⇒ less shifting reqd

Gap value -

Knuth sequence -  $(3^{k-1})/2$

k	gap
1	1
2	4
3	13
4	40

Alternative -

gap = arr.size/2

on each iteration gap = gap/2

- In place algo.
- $O(n^2)$ . Best known worst case =  $O(n \log n)$ . Best -  $O(n)$  space =  $O(1)$  but can perform much better than  $O(n^2)$
- unstable

```
for (int gap = array.length / 2; gap >= 1; gap / 2)
```

```
{
```

```
    for (int i = gap; i < arr.length; i++)
```

```
{
```

```
        int j = i;
```

```
        int partition = arr[i];
```

```
        while (j >= gap && arr[j - gap] > partition)
```

```
{
```

```
            arr[j] = arr[j - gap]
```

```
            j = j - gap
```

```
{
```

```
            arr[j] = partition;
```

```
}
```

```
5
```

```
61
```

```
51
```

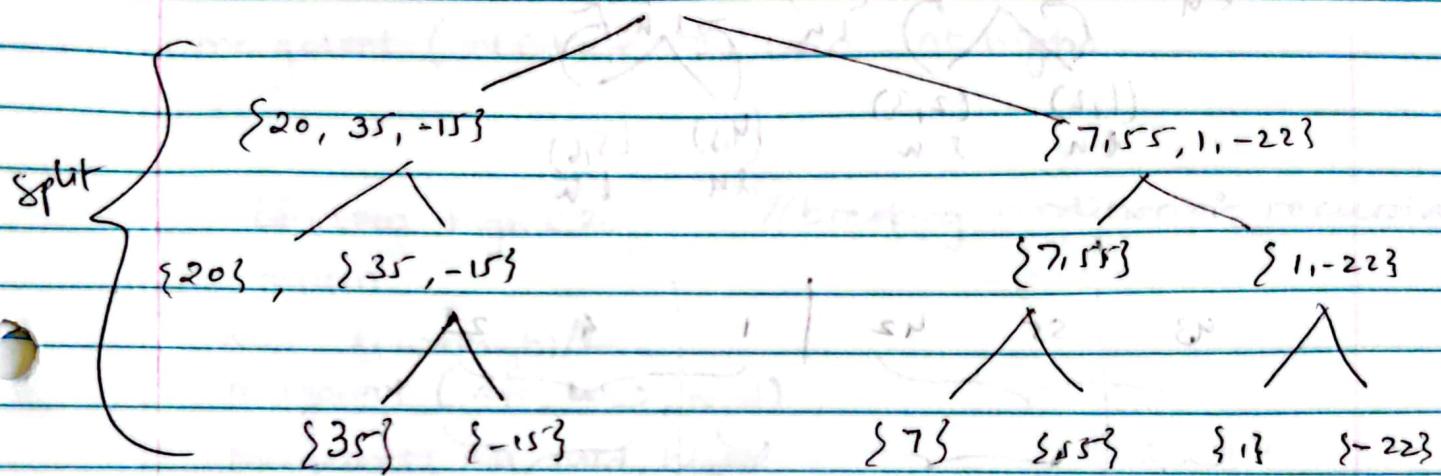

```
5
```

```
4
```

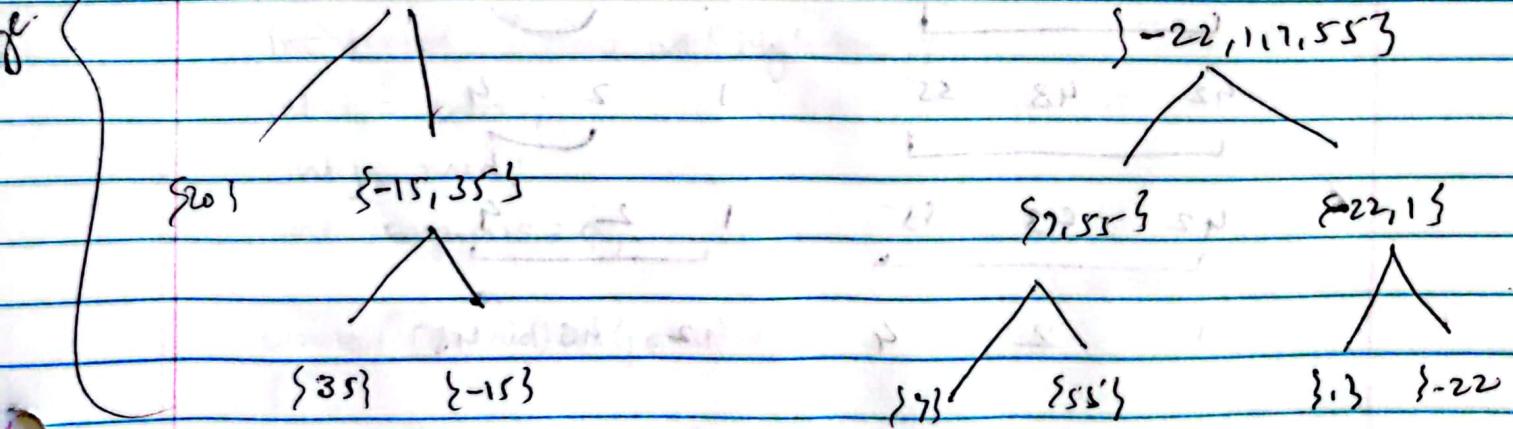

## Merge Sort

- Divide & conquer algo, recursive.
- Split & Merge.
- logical splitting, no new arrays are created.
- not in place sort, uses temp. arrays.

{20, 35, -15, 1, 7, 55, 1, -22}

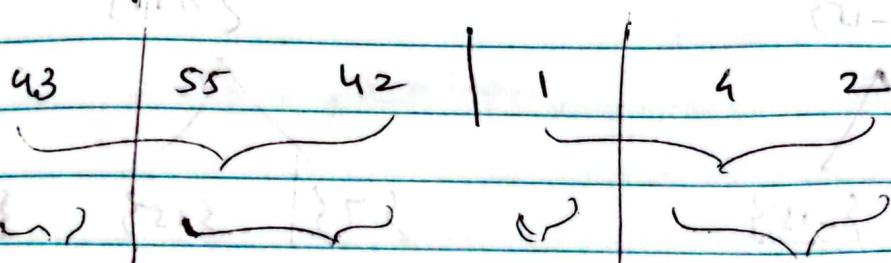

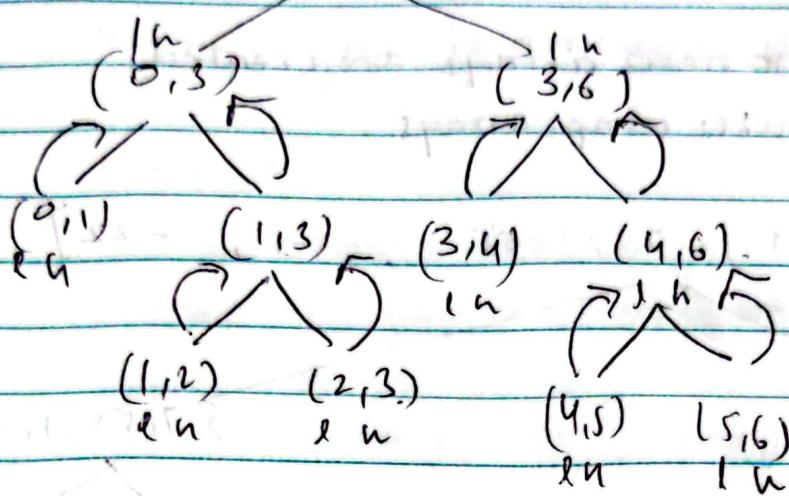

{-22, -15, 1, 7, 20, 55, 55, 1}

merge is not in place.

eg - 43, 55, 42, 1, 4, 2

mergesort (arr,  $\frac{6}{6}$ )  
(arr,  $\frac{6}{6}$ )

43 42 55 42 1 4 2

43 42 55 1 4 2

42 43 55 1 2 4

42 43 55 1 2 4

1 2 4 42 43 45

```
main ( int args[] )
```

```
{
```

```
    int arr = { 43, 55, 42, 1, 4, 2 };
```

```
    mergesort ( arr, 0, arr.length );
```

```
}
```

```
mergesort ( int [ ] arr, int low, int high )
```

```
{
```

```
    if ( low - high < 2 )
```

```
        return;
```

```
// breaking condition of recursive f
```

```
    mid = ( low + high ) / 2;
```

```
    mergesort ( arr, low, mid );
```

```
    mergesort ( arr, mid, high );
```

```
    merge ( arr, low, mid, high );
```

```
}
```

```
merge ( int [ ] arr, int low, int mid, int high )
```

```
{
```

```
    int temp [ ] = new int [ high - low ];
```

```
    int i = low;
```

```
    int j = mid;
```

```
    int temp-pos = 0;
```

```
    while ( ( i < mid ) && ( j < high ) )
```

```
{
```

```
    if ( arr [ i ] < arr [ j ] )
```

```
    {
```

```
        temp [ temp - pos ] = arr [ i ]
```

```
        i++; temp - pos++;
```

else  
{

temp[temp-pos] = arr[j];

j++; temp-pos++;

}

}

while(i < mid) // copy remaining from left array

{

temp[temp-pos] = arr[i];

i++;

temp-pos++;

}

while(j < high)

{

// copy from right array.

temp[temp-pos] = arr[j];

j++;

temp-pos++

3.

int k = 0

for(i = low; i < high; i++)

{

arr[i] = temp[k];

k++;

3.

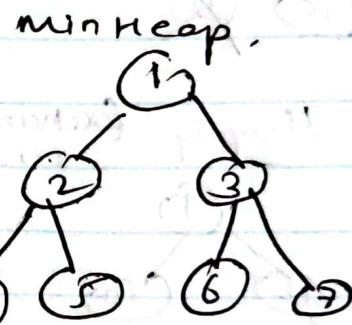

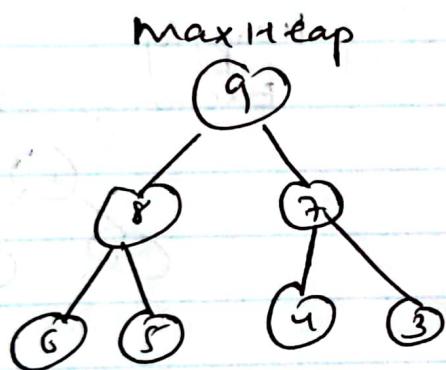

}

## Heap.

- Priority Q is an ADT, Heap is a Data Structure
- Heap is a way to implement PQ.
- PQ using array/LL  $\rightarrow O(n)$  for other operations  
 $O(1)$  for insert/ delete.
- Heap  $\rightarrow$  PQ - Insert/Delete =  $O(\log N)$ .  
max/min =  $O(1)$ .

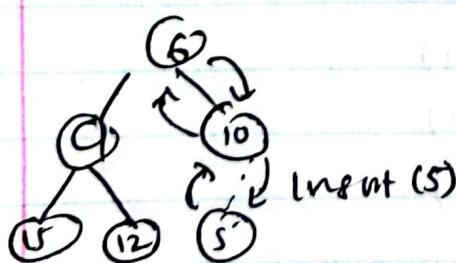

Heap:  $\rightarrow$

- a complete binary tree (all nodes filled, top to bottom, left to right)
- value of each node must be no. greater/no less than child nodes.

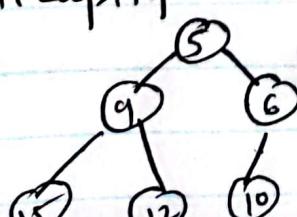

Insert.

- Insert in bottom right subtree

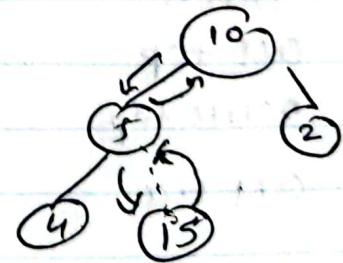

- Heapsify.

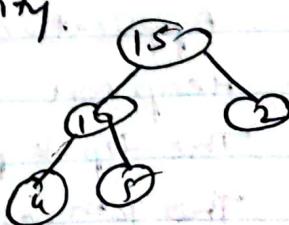

max heap.

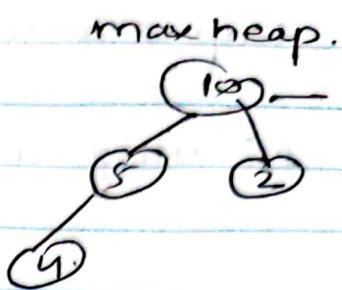

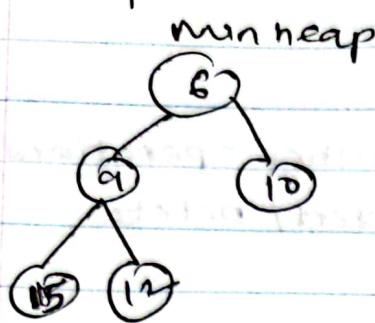

- Insert into bottom of left

- Heapsify.

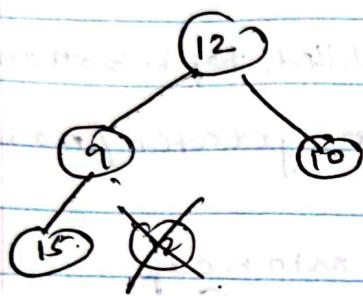

## Heap Deletion.

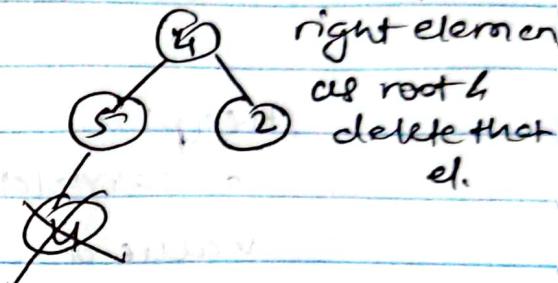

Delete 6

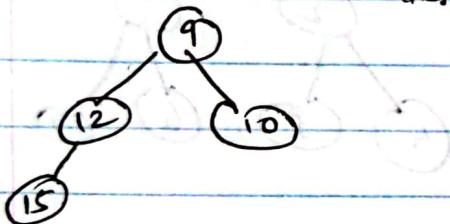

move bottom leftmost  
element to root & delete  
that

Delete 10, make bottom

Heapify - Exchange with  
smallest child

Heapify:

Exchange with target child

Method

Time

Space

construct

$O(N)$

$O(N)$

$O(N \log N)$

$O(1)$

get top

$O(1)$

$O(1)$

delete top,

$O(N \log N)$

$O(1)$

get size,

$O(1)$

$O(1)$

## Applications

\* Heap sort -  $O(N \log N)$  space  $O(N)$

\* The top-k problem.  $O(N + k \log N)$

\* The  $i$ th element. - - -

## maxheap (PQ)

PriorityQueue<Integer> maxHeap = new PQ<>(Collections.reverseOrder());

maxHeap.add(1)

—II— (3);  
—II— (2);

↓  
for min heap  
don't use this

Op - maxHeap.toString()

maxHeap.peek()

maxHeap.poll()

maxHeap.size()

maxHeap.isEmpty()

PQ fns -

add(E e)

clear() → remove all.

comparator()

contains(Object o).

iterator()

offer()

peek()

poll()

remove(o)

size()

toArray()

toArray(~~T[] a~~)

## Heap applications

Heap sort -  $O(n \log n)$

Top k problem. &  $k^{\text{th}}$  element — similar approach.

Approach 1: top k largest elements

1. Construct max heap
2. Add all elements to it —  $O(n)$
3. Traversing & deleting top element (pop() / poll()) and store value in result array T. —  $O(k \log n)$
4. Repeat 3 until we have removed  $k$  largest elements.

Time -  $O(k \log n) + O(n)$  Space -  $O(n)$ .  
 $= O(n + k \log n)$ . Step 2)

Similar for smallest k elements.

Approach 2: top k largest elements.

1. Construct a min heap
2. Add elements to min heap one by one
3. When there are  $k$  elements in min heap compare current element with the top element of heap.
4. If curr is no larger than top, drop it and proceed to next.
5. If curr is larger than heap's top element, add the curr to min heap.
6. Repeat steps 2 & 3 until all elements have been iterated.

Now the  $k$  elements in min heap are  $k$  largest elements

Time:  $O(n \log k)$

$O((N-k) \log k + k \log k) = O(n \log k)$

Space -  $O(k)$ .

(Implementation) array

array solution

disadvantages

## Queues

- ADT

- FIFO, first in first out.

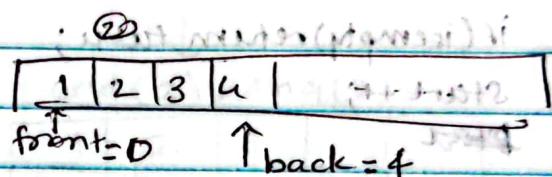

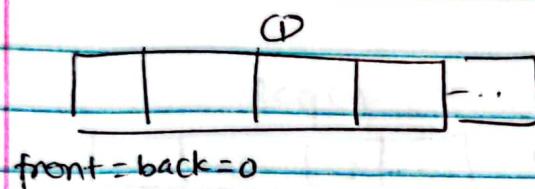

O - time + space  
Implementation

(x) time, space

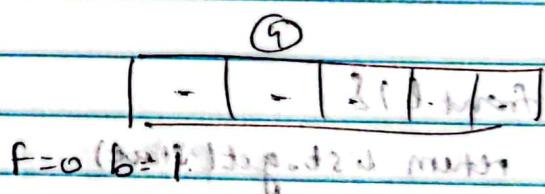

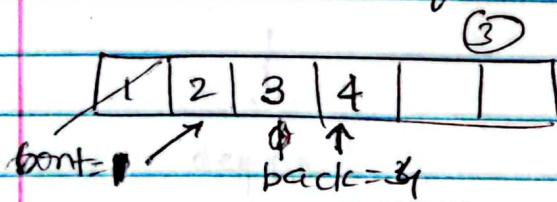

enqueue => add to end of queue.

dequeue => remove from front

peak => get item at front but don't remove it.

(front is 0 always)

empty

empty & front = back >= 1 => full

empty & front <= back >= 1 => empty

front = back = empty

## Queue (linkedlist)

Queue using linkedlist -

start = 0;

list (array)

```

```
{
```

```
    return queue[front];
```

```
}
```

## Circular Queue:

what if u have only  $n$  elements at a time in a queue.

You don't have to resize

eg - queue of size 5

[null] null [null] null [5]

↑  
front back

so when we add new element, it is  
resized even though we have 4 empty  
spaces.

enqueue( Emp e ) :

{

if (size() == queue.length - 1)

{

int num\_items = size();

if resize

System.arraycopy(queue, front, newQueue, 0, queue.length - front)  
————— (queue, 0, newQueue, queue.length - front, back)

queue = newQueue;

front = 0;

back = num\_items;

3.

queue[back] = e;

if (back < queue.length - 1)

{

back++

}

else

{

back = 0

3

size()

{

if (front <= back) return back-front

else return back-front + queue.length;

}

dequeue

{

if (size() == 0)

} //no element exception

{

Emp e = queue[front];

queue[front] = null;

front++;

if (size() == 0)

} front = back = 0; //push

{

else if (front == queue.length)

{

front = 0;

5.

return e;

{

printQueue()

{

if (front <= back)

{ for i → front to back

print

```
else
{
    for (i = front; i < queue.len; i++)
    {
        //print
    }
    for (i = 0, i < back, i++)
    {
        //print
    }
}
```

Time -  $O(1)$  - if not resizing,  
 $O(n) \rightarrow$  if resizing

## Java built-in queues.

Queue<Integers> q = new LinkedList();

q.peek();

q.offer(5);

q.offer(3);

q.offer(8); //push

q.poll(); //pop

q.size(); //size.

(will discuss in Q & A) ~~in~~

• ~~Implementation of Queue~~

### CircularQueue

```
list<int> queue = new linkedlist<int>;  
front = back = 0;  
int capacity;
```

size().

```
{ if (front == rear) return r-f;  
    return r-f + capacity;
```

}

enqueue(x)

```
if (queue.size < capacity)  
{
```

queue.add(x)

rear++;

return

}

```
if (queue.size == capacity)
```

{

```
if (size == capacity)
```

return

else,

```
if (f <= r)
```

{

r = 0

```
queue.set(rear, x);
```

}

r++

dequeue()

{

```
if (size == 0) return
```

```
if (front == rear)
```

{

if f == 0

r = 0

return

}

front++

{

else

```
queue.add(x)
```

r++

{

3

Stacks - an ADT.

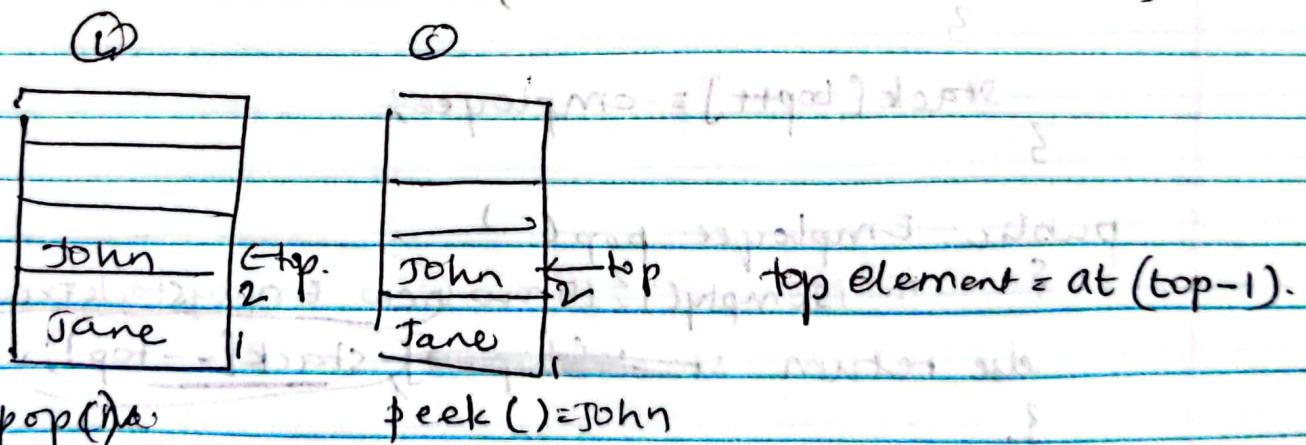

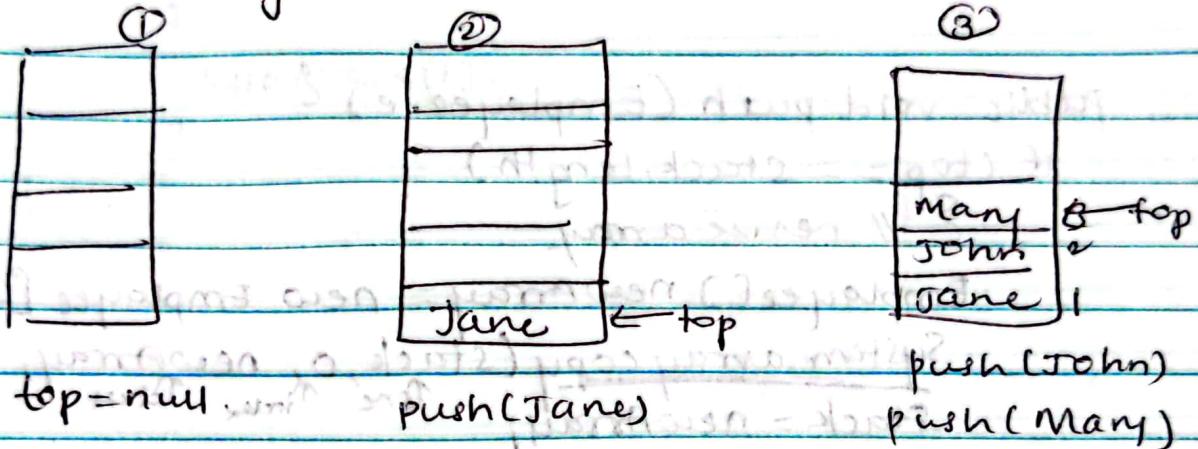

LIFO → Last In First Out. ~~first implemented~~ stacks

push: add an item to top.

pop - removes top item ~~last~~ ~~bottom~~ ~~bottom~~

peek → get top item without removing.

Ideal backing DS - linked list -

Time-	Push	Pop	Peek
Linked list	$O(1)$	$O(1)$	$O(1)$
Array	$O(n)$	$O(1)$	$O(1)$

(good if u know max items, so array needs not resized)  
memory is tight <sup>then</sup> → arrays  
else linked list

```
public class Arraystack {
```

```
    private Employee[] stack;  
    private int top; // = 0 initially
```

```
    public Arraystack (int capacity)
```

```
    {  
        Stack = new Employee[capacity];  
        top = -1;
```

```
        public void push (Employee e) {
```

```
            if (top == stack.length - 1)
```

```
                // resize array.
```

```
                Employee[] newStack = new Employee[2 * stack.length];
```

```
                System.arraycopy (stack, 0, newStack, 0, stack.length);
```

```
                stack = newStack;
```

```
            }  
            stack[top + 1] = employee;
```

```
        }  
    }
```

```
    public Employee pop ()
```

```
    {  
        if (isEmpty ()) throw new EmptyStackException();  
        else return stack[--top];  
    }  
}
```

```
    public boolean isEmpty ()
```

```
    {  
        return top == 0;
```

```
    }  
}
```

```
    public Employee peek ()
```

```
    {  
        if (isEmpty ()) throw new EmptyStackException();  
        return stack[top - 1];  
    }  
}
```

top here

public int size()

return top;

public void printstack()

{  
for (int i = top - 1; i >= 0; i--) {

System.out.print(stack[i]);  
System.out.print(" ");  
}

System.out.println();

System.out.println();

System.out.println("Stack is empty");

System.out.println();

## Stacks - linkedlist

// use class for abstraction  
else everyone will call  
any other fn of linkedlist

```
public class linkedstack {  
    private linkedlist<Employee> stack;  
    public linkedstack()  
    {  
        stack = new linkedlist<Employee>(stack);  
    }
```

```
3  
Stack = new linkedlist<Employee>();
```

```
public void push(Employee e)  
{  
    stack.push(e);  
    —————— stack.add(0)
```

```
3
```

```
public Employee pop()  
{  
    return stack.pop();  
}
```

```
→ stack.remove(stack.size() - 1)
```

```
3
```

```
public Employee peek()  
{  
    → stack.get(stack.size() - 1)  
    return stack.peek();  
}
```

```
3
```

```
public boolean isEmpty()  
{  
    → return stack.isEmpty();  
}  
3
```

```
3
```

## Java built-in stack

Stack<integer> s = new Stack<c>;

```
s.push(1)  
s.push(2)
```

```
if(s.isEmpty() == true) {  
    System.out.println("Stack is empty");  
}
```

```
s.pop();  
return;
```

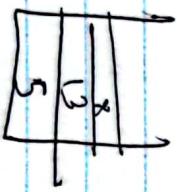

3

```
s.pop(); // 1  
s.pop(); // 2
```

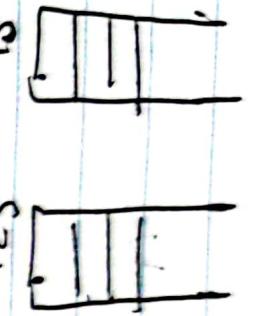

```
s.size // 0
```

Search: finds element

```
search(st) = 3
```

## Stack Queue using 2 stacks

push(x)

```
{  
    if(S2.isEmpty())  
        while(S1.isEmpty())  
            S2.push(S1.pop())  
    S1.push(x)  
    return S2.pop()
```

pop

```
{  
    if(S2.isEmpty())  
        while(S1.isEmpty())  
            S2.push(S1.pop())  
    S1.pop()  
    return S2.pop()
```

3

peek()

```
{  
    if(S1.isEmpty())  
        return S2.isEmpty()  
    S2.push(S1.pop())  
    S1.pop()  
    return S2.pop()
```

empty

```
{  
    if(S1.isEmpty() &  
       S2.isEmpty())  
        return 1  
    else  
        return 0  
}
```

return S2.peek()

3

### Abstract data type

- Doesn't dictate how data is organised  
(eg arrays are organised, list are not.)
- Dictates the operations you can perform
- Concrete data structure is usually a concrete class
- Abstract data type is usually an interface.

### ArrayList

- initial capacity by default = 10
- .add()
- .get(index)
- .isEmpty()
- .set(2,"Johnx")
- .size()
- .add(3,"Does")
- .toarray() → convert to array
- .contains(obj)
- .indexof
- .remove(3)

vector: when u have to be thread-safe

⇒ when synchronization is needed

→ slower than ArrayList .

## linkedlist

head.

Insert.  
at start —

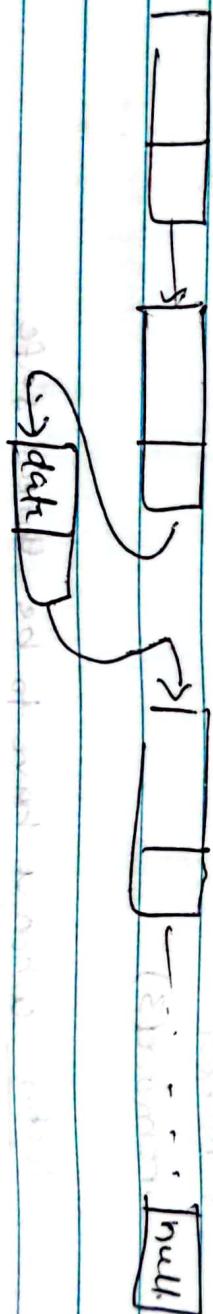

at end.

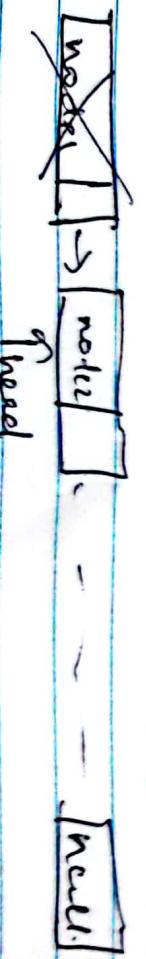

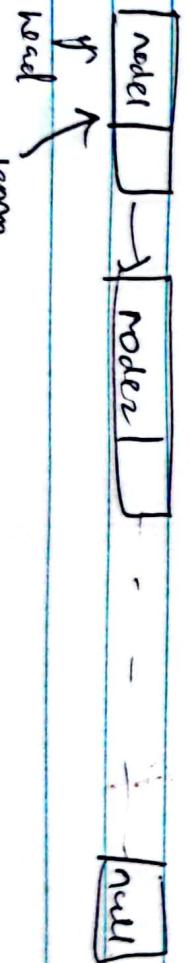

at end

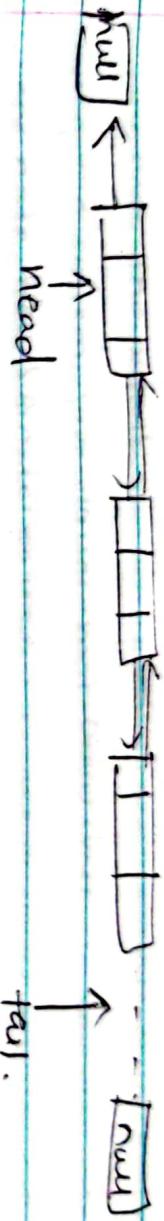

render pos.

Similarly deletion.  
first node

## Doubly linked list-

// Task - Implement SL, DL, List out list methods.  
addfirst, addlast etc.

Tree - a hierarchical data structure

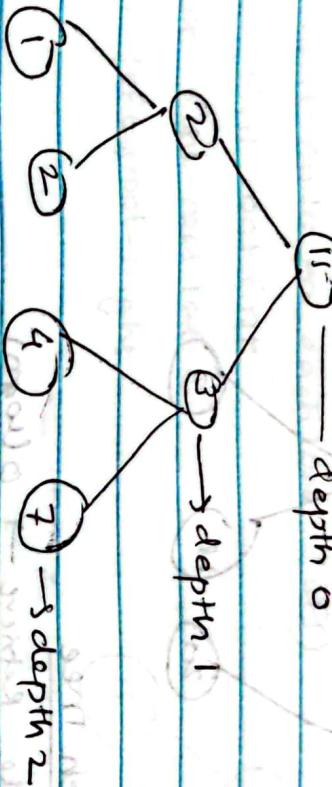

nodes, children edges, parent (only one at max)

- root → no parent.

eg - file system, java classes - root - object class

- one node tree → singleton tree.

- no cycles.

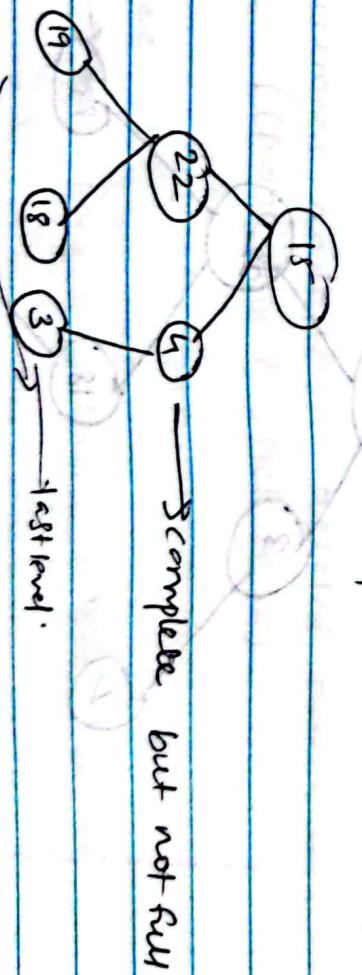

height → no. of edges to longest path from root to leaf

Binary Tree.

- Every node has 0, 1 or 2 children.
- left & right child.

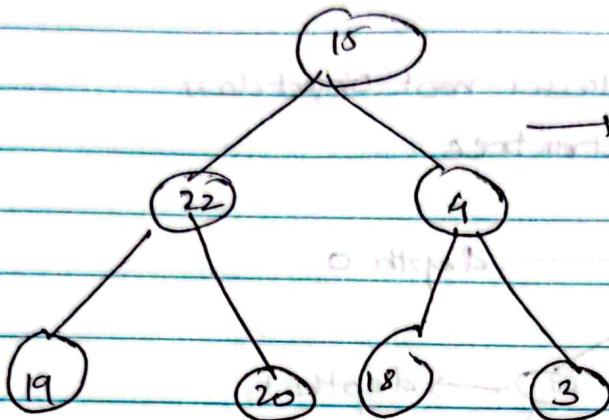

Complete Binary Tree - if every level except last one has 2 children  
and in last level all nodes are as left as possible

→ complete but not full

full binary tree - complete

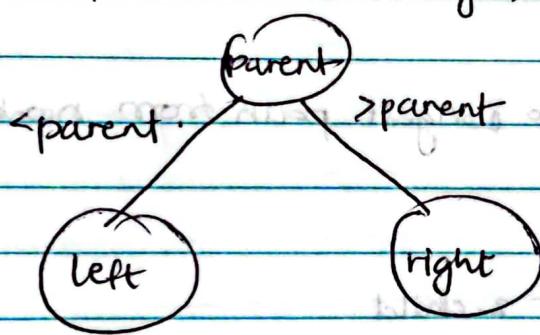

every node except leaf has 2 children

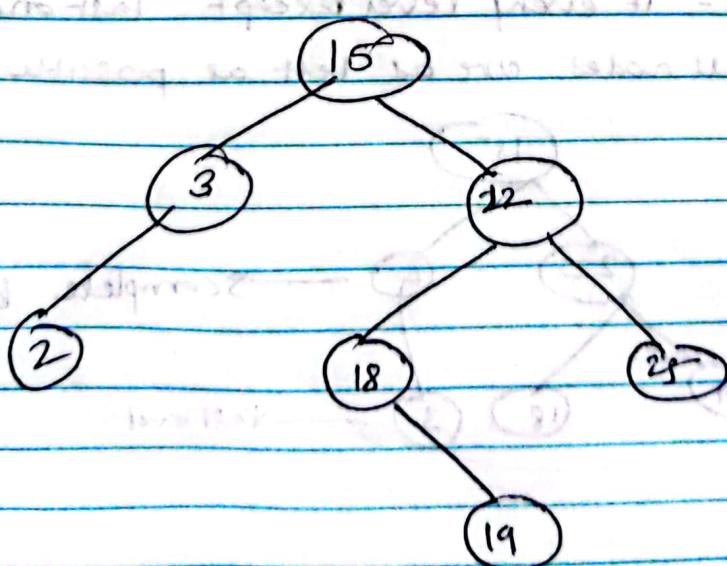

→ full

### Binary search tree

Insert, Delete, Retrieve →  $O(\log n)$ .

search -  $O(\log n)$

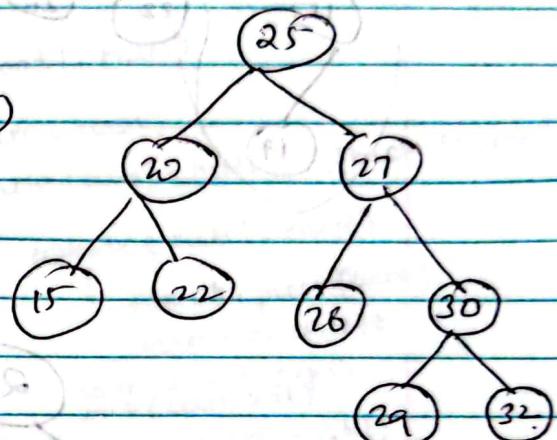

duplicate not allowed  
or store in fix slot (L or R)

- min → left edge till leaf
- max → right edge till leaf.

AVL, Red Black → \*

### Traversal

- 1) Level → visit nodes on each level (BFS)
- 2) Preorder - visit root first
- 3) Postorder - visit root last
- 4) Inorder - left, root, right

Level 25, 20, 27, 15, 22, 26, 30, 29, 32

Preorder 25, 20, 15, 22, 27, 26, 30, 29, 32

Postorder 15, 22, 20, 26, 27, 30, 32, 29, 25

Inorder 15, 20, 22, 25, 26, 27, 29, 30, 32. — sorted data

### Delete -

1) Leaf — remove

2) Node has one child → replace child by node

3) 2 child.

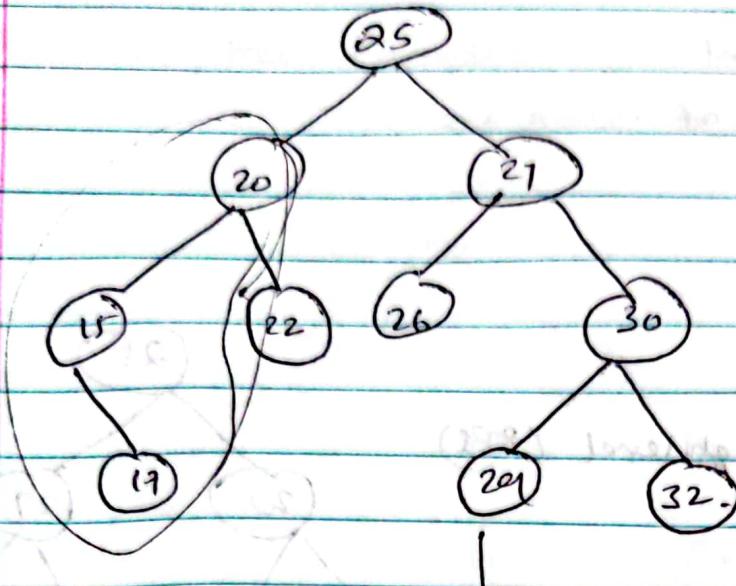

Can take replacement node from deleted node's left subtree or right subtree (Choose one & stick to it)

IF left subtree

→ take largest value in left subtree

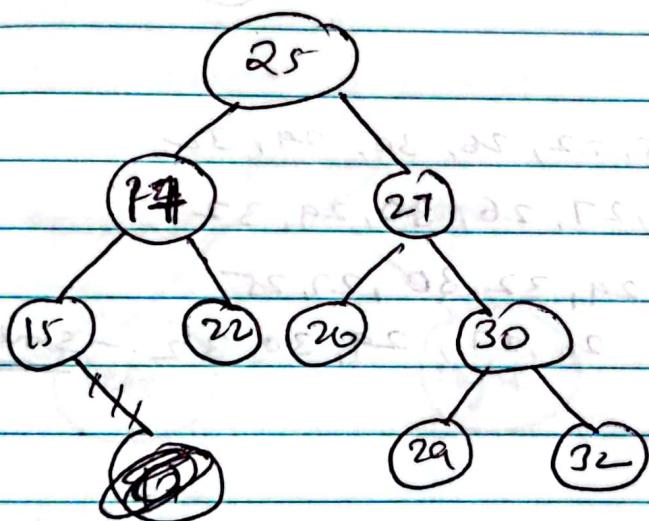

IF right subtree

→ take smallest value in right subtree

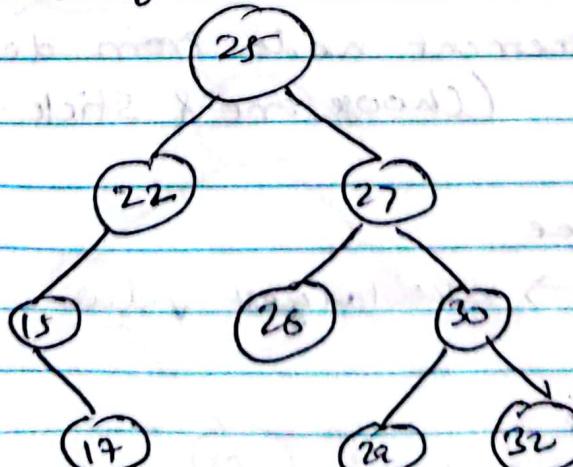

delete - 20,

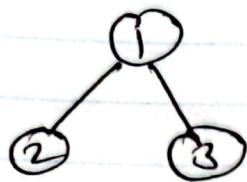

(left subtree)

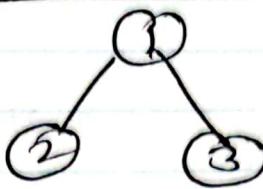

Delete 20 (Right subtree)

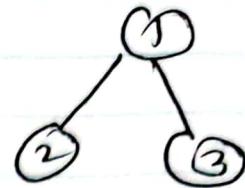

## Tree Traversals

Inorder  
left - root - right  
2 - 1 - 3

Preorder  
root - left - right  
1 2 3

Postorder  
left - right - root  
2 3 1

level order  $\Rightarrow$  BFS.

Inorder (Treenode root)

```
{
    if(root!=null)
    {
        inorder(root.left)
        sop(root.val)
        inorder(root.right)
    }
}
```

3

3:

Preorder (Treenode root)

```
{
    if(root!=null)
    {
        sop(root.val)
        preorder(root.left)
        preorder(root.right)
    }
}
```

3

3:

Postorder (Treenode root)

```
{
    if(root!=null)
    {
        postorder(root.left)
        postorder(root.right)
        sop(root.val)
    }
}
```

3

if(root!=null)

```
{
    curr=root;
    while(curr!=null || !stack.isEmpty())
    {
        while(curr!=null)
        {
            stack.push(curr)
            curr=curr.left;
            curr=stack.pop()
            sop(curr.val);
            curr=curr.right;
        }
    }
}
```

3

stack.push(root)

```
{
    curr=root;
    while(!stack.isEmpty())
    {
        if(curr.right!=null) stack.push(right)
        if(left == null) --right
        curr=stack.pop()
        sop(curr.val)
    }
}
```

3

Stack<Treenode> stack = new Stack<Treenode>;  
stack.push(root);

```
while(!stack.isEmpty())
{
    curr=stack.pop();
    if(curr.left==null || curr.right==null)
    {
        stack.push(curr);
        if(right==null) stack.push(curr.right);
        else if(left==null) stack.push(curr.left);
        else sop(curr.val);
    }
}
```

## Tree Traversal

Preorder traversal - (root, left, right)

preorder(root)

```

    if (root == null) return res;
    res.add(root.val);
    preorder(root.left);
    preorder(root.right);
    return res;
}

```

O(n) Time & Space

Inorder (left, root, right).

inorder(root)

```

    if (root == null) return res;
    inorder(root.left);
    res.add(root.val);
    inorder(root.right);
    return res;
}

```

O(n) Time & Space

preorder(root)

```

    if (root == null) return res;
    Stack<Tree> st = new Stack<Tree>();
    st.push(root);
    while (!st.isEmpty())
    {
        TreeNode node = st.pop();
        res.add(node.val);
        if (node.right != null) st.push(node.right);
        if (node.left != null)
            st.push(node.left);
    }
    return res;
}

```

Time - O(n) O(n) - Space

inorder(root)

{

```

        if (root == null) return root;
        Stack<TreeNode> st = new Stack<TreeNode>();
        TreeNode curr = root;
        while (curr != null || !st.isEmpty())
        {
            if (curr != null)
                st.push(curr);
            curr = curr.left;
        }
    }

```

while (curr != null)

{

```

            st.push(curr);
            curr = curr.left;
        }
    }

```

curr = st.pop()

res.add(curr.val)

curr = curr.right;

{

return res;

}

O(n) - Time & Space

## Height balanced BST

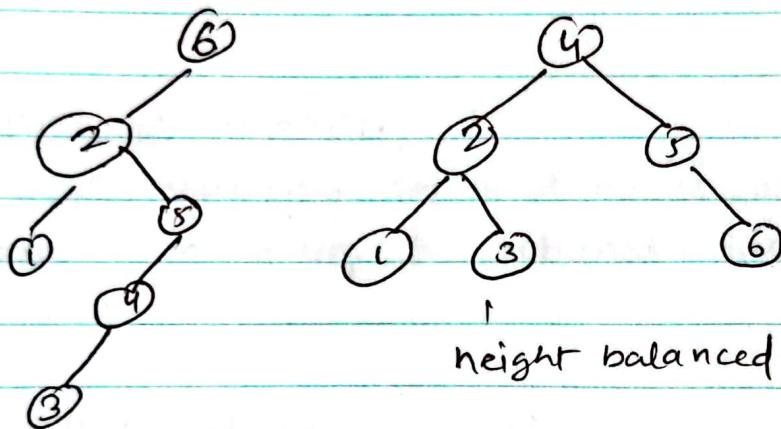

Depth of a node  $\rightarrow$  no. of edges from root to the node.

height of a node = no. of edges on longest path between that node and leaf

height of tree = height of root.

Height balanced BST -

- height is  $\log(N)$   $\rightarrow N = \text{no. of nodes}$
- height of two subtrees of every node never differs by more than 1.

normal BST

- improves performances
- as in BST most ops time depends on height  $O(h)$   
 $\therefore$  if height is  $\log N$  time is reduced from  $N$  to  $\log N$ .

Popular height balanced BST.

- Red black tree
- AVL tree
- Splay tree
- Treap
- In Java: ~~set~~ or TreeSet OR C++: set it is implemented using height balanced BST : time =  $O(\log N)$

Also in HashSet, it is implemented by hash but if there are too many elements with same hash key it will cost  $O(N)$  to look for a specific element. where  $N$  is no. of elements with same hash key. Typically, height balanced BST will be used here to improve performance from  $O(N)$  to  $O(\log N)$ .

↳ Implementation

## Top-Down / Bottom-up.

### Topdown (preorder).

first visit the node to come up with some values and pass these values to its children while calling the fn recursively.

eg.

return if root is null

if root is a leaf :

answer = max(answer, depth)

max-depth (root.left, depth+1)

max-depth (root.right, depth+1)

### Bottom up (postorder)

call fn recursively for children node and then come up with answer according to returned values and value of curr node itself.

eg.

return 0 if root is null.

left-depth = max-depth (root.left)

right-depth = max-depth (root.right).

return max(left-depth, right-depth)+1.

## BFS & DFS.

(Ch 10) 10 - 19

BFS - Template - 1. (Shortest path b/w root & target)

int BFS (Node root, Node target)

Queue<Node> queue;

int step = 0;

add root to queue;

while(queue.is not empty)?

int size = queue.size();

for (i=0 to size)

{

Node cur = the first node in queue;

return step if cur is target;

for (Node next : neighbor of cur),

{

add next to queue;

}

remove first node from queue;

}

step = step + 1;

{

return -1;

}

## BFS - II (visited)

```
int BFS ( Node root, Node target ) {  
    Queue<Node> queue;  
    set<Node> visited;  
    int step = 0;  
  
    add root to queue;  
    add root to visited;  
  
    while ( !queue.isEmpty() ) {  
        int size = queue.size();  
        for ( i = 0 to size ) {  
            Node cur = first node in queue;  
            return step if cur == target;  
            for ( Node next : in neighbors of cur ) {  
                if ( next is not in visited ) {  
                    add next to queue;  
                    add next to visited;  
                }  
            }  
            remove first node from queue;  
        }  
        step = step + 1;  
    }  
    return -1;  
}
```

DFS - Path may not be shortest.

### DFS

I) `boolean dfs(Node cur, Node target, Set<Node> visited) {`  
    `return true if cur == target;`  
    `for (next: each neighbour of cur) {`  
        `if (next is not in visited)`  
            `{`  
                `add next to visited;`  
                `return true if dfs(next, target, visited) == true.`  
            `}`  
        `}`  
    `return false;`  
}

### II) Iterative

`boolean dfs (int root, int target)`  
{

`Set<Node> visited;`  
    `Stack<Node> stack;`  
    `add root to stack;`  
    `while (stack is not empty)`  
        `{`

`Node cur = remove top element from stack;`

`return true if cur is target;`

`for (Node next: neighbors of cur)`

`{`

`if (next is not in visited)`

`{`

`add next to visited;`

`add next to stack;`

`}`

`}`

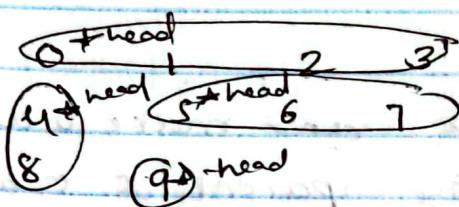

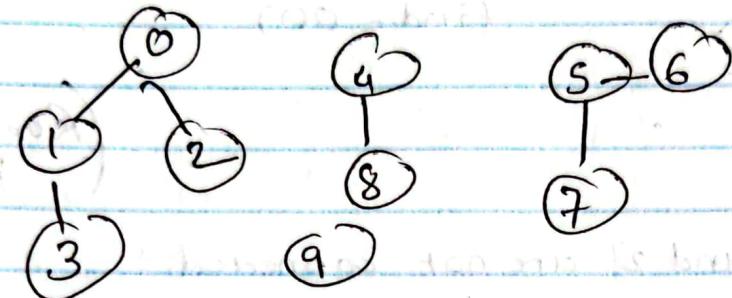

`return false;`

## Graphs

- a non linear data structure consisting of vertices & edges.

### Disjoint set / Union find

- used to find connectivity b/w components of a network

### Union

(0,1) (0,2) (0,3)  
(4,8) (5,6) (5,7)

check if connected -

(0,3)      (4,5)      (7,8)  
same head      X      X

1) Find: finds root of given vertex. eg. root of 6 is 5

2) Union: unions two vertices and makes their root nodes same

2 ways to implement disjoint set

#### Quickfind

- find faster  $O(1)$   
union -  $O(N)$

#### Quick Union

Union faster. -  $O(N)$ -worst case. So  
find takes more time -  $O(N)$ .

- more efficient than Quickfind

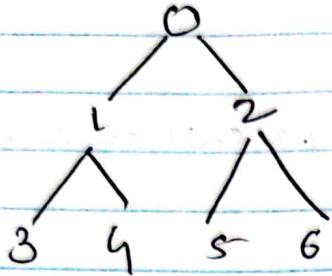

Worst case connect n

elements  
 $O(N^2)$

$\leq O(N^2)$

### Quick Find

- store root nodes directly.

Arrayval : 0 0 0 0 0 0

Arrayindex : 0 1 2 3 4 5 6

find - O(1)

(Root stored directly  
in the array)

### Union-

Suppose 0 and 2 are not connected.

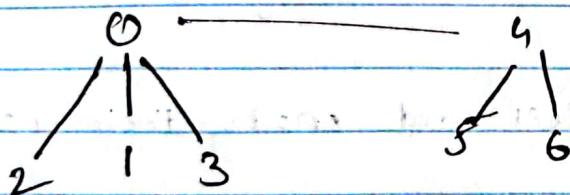

$$\text{Parent}(0) = 0$$

$$\text{par}(2) = 2$$

now we connect 0-2 and make 0 as parent  
then we have to change parents of 5, 6 and so on.  
O(N)

### Quick Union

(We need to traverse to find root)

(0,1)      (4,1)  
(1,2)      (4,5)  
(1,3)      (1,5)

(find parent & connect them)

Arrayval : 0 0 0 0 0 0 0

ind    0    1    2    3    4    5    6

Space -  $O(n)$

Construct Find Union Connected

$O(n)$   $O(1)$   $O(n)$   $O(1)$

Quick find

```
int find(x)
```

```
    return root[x]
```

more efficient  
Space -  $O(n)$

$O(n)$   $O(n)$   $O(n)$   $O(n)$

Quick union.

```
int find(x)
```

```
    if x == root[x]
```

```
        return x;
```

```
    return root[x] = find(root[x])
```

```
void union(x, y)
```

```
    rootx = find(x)
```

```
    rooty = find(y)
```

```
    if (rootx != rooty)
```

```
        for (i in 0 to root.length)
```

```
            if root[i] == rooty
```

```
                root[i] = rootx;
```

```
void union(x, y)
```

```
    rootx = find(x)
```

```
    rooty = find(y)
```

```
    if rootx != rooty
```

```
        root[rooty] = rootx;
```

connected

```
return find(x) == find(y)
```

### Union by Rank

- Choose root of taller tree.
  - is an optimization for quick union
- Find -  $O(\log n)$        $O(\log n)$   
Union -  $O(\log n)$        $O(\log n)$   
Connected -  $O(\log n)$        $O(\log n)$ .

### Path Compression

- update root nodes of all traversed elements
- so next time u only have to travel 2 nodes.
- optimized find function

— why is quick union more eff?

Quick find -  $O(n)$  - union

Quick union -  
find operation - const case

Union find constructor

$O(n)$

find

$O(\alpha(N))$

Union

$O(\alpha(N))$

connected

$O(\alpha(N))$

$O(\alpha(N)) \Rightarrow O(1)$  on average

Space  $O(n)$

## Minimum Spanning Tree (MST)

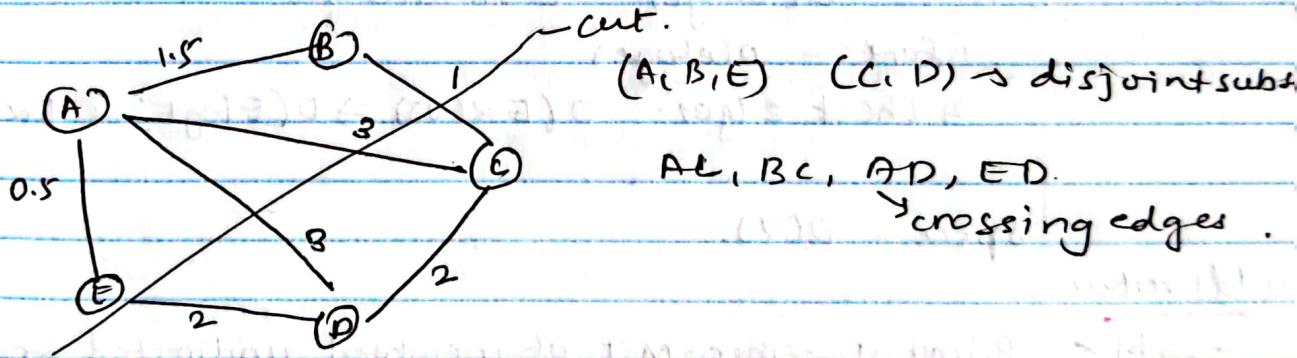

Spanning tree → is a connected subgraph in an undirected graph where all vertices are connected with minimum number of edges.

- An undirected graph can have multiple spanning trees.

MST - min cost spanning tree

Cut → is a partition of vertices in a graph into two disjoint subsets.

A crossing edge → is an edge that connects a vertex in one set with a vertex in other set.

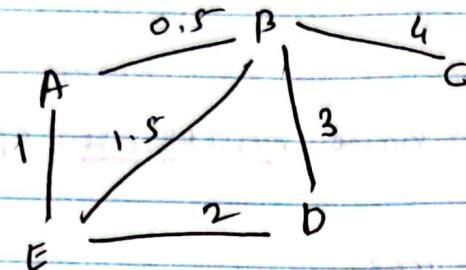

Cut Property:

For any cut  $C$  of the graph, if the weight of an edge  $E$  in the cut-set of  $C$  is strictly smaller than the weights of all other edges of cut-set of  $C$ , then this edge belongs to all MSTs of the graph.

Kruskal's algorithm - MST. of weighted undirected graph

argy

AB 0.5

AE 1

BE 1.5

ED 2

BD 3

BC 4

MST.

$\rightarrow [AB, AE, ED, BC]$

$$n-1 = 5-1 = 4.$$

1) Ascending sort all edges by their weight.

2) Add edges in that order in MST. Skip edges that would produce cycles in MST.

3) Repeat step 2 until  $n-1$  edges are added.

Time -  $O(E \log E)$  - E-edges.

1) for E -  $O(\log E)$

2) Check edge -  $O(E \alpha(V)) \Rightarrow O(E \log E + E \alpha(V)) = O(E \log E)$ .

Space -  $O(V)$ .

Prim's Algorithm - MST of weighted undirected graph

2 sets - visited, unvisited

At each step take one vertex from unvisited, add it to visited & select min <sup>weight</sup> of edge going out of all visited edges

visited A . A B F A B E A B E D A, B, C, D E

non visited B C D E C D E C P B C -

edge AB, AE, ED, BC.

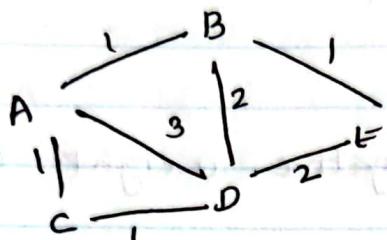

Time  $O(E \log V)$

Space  $O(V)$ .

## Single Source shortest Path Algorithm

Shortest path in a weighted graph.

Edge relaxation:

A      B      1  
       C      1  
       D      ?  
       E      ∞. But  $A-C-D = 2$  is shorter  
                 (no connection directly)

This is relaxation.

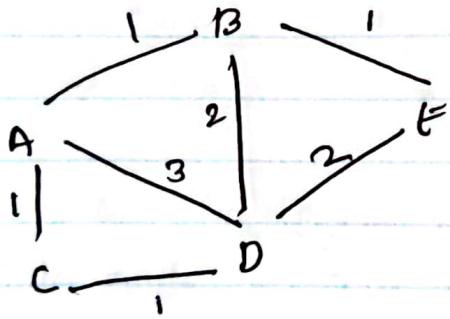

Dijkstra's - (only in graph with non negative weights).

Bellman Ford (weighted directed graph along with ~~non~~ negative weights).

Dijkstra's - uses a greedy approach.

We take a starting point  $a$  as the center and gradually expand

outward while updating shortest path to reach other vertices.

Select next vertex with min cost.

Target vertex	shortest dist	prev vertex
1 (A)	0 0 0 0 0	0
2 (B)	0 1 1 1 1	1
3 (C)	0 1 1 1 1	1
4 (D)	0 3 2 2 2	2
E	0 0 0 0 2	B

does not work for negative weights.

Time -  $O(E + V \log V)$ .

Space -  $O(V)$ .

## Bellman Ford

- handles negative weight graphs.

Theorem 1: In a graph with no negative-weight cycle, with  $N$  vertices, the shortest path between any vertices has atmost  $N-1$  edges.

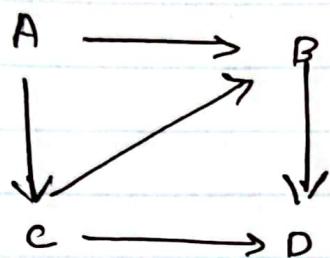

Theorem 2: In a graph with negative weight cycle there is no shortest path

## Kahn's Algorithm for topological sorting

course A → B → C → D

for D, we must first complete C, for C → B and so on.

Given vertices u and v to reach vertex v, we must have reached u first. In topological sorting u has to appear before v in the ordering.

A has no prereq.  
B requires A, C.  
C req. A  
D req. B, C.

Topological order - [A, C, B, D]

Queue - [A] - -

[X] [B] - -

[X] [X] [B] -

[X] [X] [B] [D]

In degree - edges in

out degree - edges out

Calculate in degree for all nodes.

Add node with 0 in degree to queue

Poll from queue and mark that node visited

Subtract 1 from all nodes who have A as prereq

If indegree becomes 0 add it to queue

repeat

Time -  $O(V \cdot E)$ .

Iterate over E prereq for V nodes. } without adjacency list

Space -  $O(V)$  - store indegree

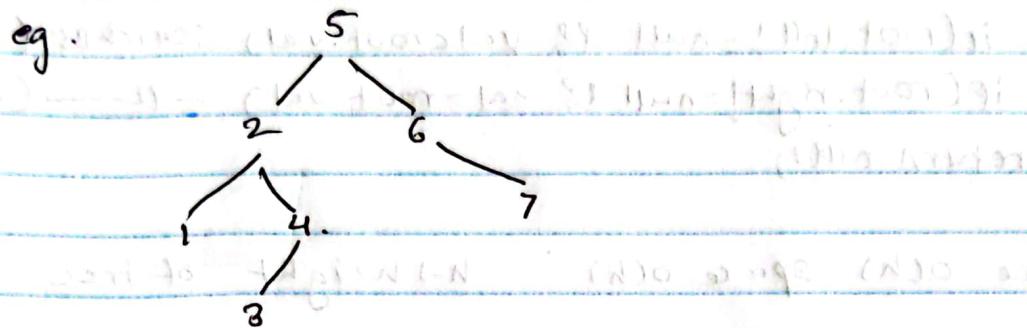

For a cyclic graph, there is no topological sorting.

Works only for directed acyclic graphs.

Time  $O(V+E)$  Space -  $O(E)$  → using adj list.

## Binary Search Tree.

- A special form of binary tree.
- The value in each node must be greater than (or equal to) any values in its left subtree but less than or equal to any values in right subtree.

- \* Inorder traversal in BST will be in ascending order.

### Search - Iterative

class Solution{

    public TreeNode searchBST(TreeNode root, int target){

        TreeNode cur = root;

        while(cur!=null && cur.val!=target){

            if(target < cur.val){

                cur = cur.left;

            }

            else cur = cur.right;

        }

    return cur;

}

time - O(h) space(O(1)).

## Search - recursive

```
'searchBST( root, val )
```

```
{
```

```
    if( root == null ) return null;
```

```
    if( root.val == val ) return root;
```

```
    if( root.left != null && val < root.val ) searchBST( root.left, val );
```

```
    if( root.right != null && val > root.val ) searchBST( root.right, val );
```

```
    return null;
```

```
}
```

Time O(h) Space O(h) h → height of tree

## Insert - Iterative Time - O(h) Space O(1).

```
public TreeNode insert( TreeNode root, int val ).
```

```
{
```

```
    TreeNode curr = root;
```

```
    if( root == null ) return new TreeNode( val, null, null );
```

```
    while( true )
```

```
{
```

```
    if( val > curr.rightval )
```

```
{
```

```
        if( curr.right != null )
```

```
            curr = curr.right;
```

```
        }
```

```
        else break;
```

```
}
```

```
else {
```

```
    if( curr.left != null )
```

```
        curr = curr.left;
```

```
    else break;
```

```
}
```

```
if( val > curr.val ) curr.right = new TreeNode( val, null, null );
```

```
else
```

```
    curr.left = null;
```

```
return root;
```

## Insert - Recursive

```
insert {
    if (root == null) return new TreeNode(val);
```

```
    if (val > root.val) root.right = insert(root.right, val);
```

```
    else root.left = insert(root.left, val);
```

```
    return root;
```

```
}
```

Time  $O(h)$ , Space  $O(h)$

## Deletion - Recursive

\* Predecessor = before node

    ⇒ previous node or largest node before current one

\* Successor = smallest node after current one  
    = after node

case 1: if node is leaf → delete

case 2: - node has right child.

    replace node by its successor. Then recursively delete successor

case 3: node has left child, no right child

    replace node by its predecessor. Then recursively delete predecessor

```
public int successor(TreeNode root) { ... // one right, then leftmost }
```

```
    root = root.right;
```

```
    while (root.left != null) root = root.left;
```

```
    return root.val;
```

```
}
```

predecessor

```
? root = root.left;
```

```
while (root.right != null) root = root.right;
```

```
return root.val
```

```
}
```

// one left, then rightmost

```

public TreeNode deleteNode (root, key) {
    if (root == null) return null;
    //delete from right subtree
    if (key > root.val) root.right = deleteNode (root.right, key);
    else //delete from left subtree.
        if (key < root.val) root.left = deleteNode (root.left, val);
    //delete the current node
    else {
        //node is leaf
        if (root.left == null & root.right == null) root = null;
        //node is not a leaf, has right child .
        else if (root.right != null),
        {
            root.val = successor (root);
            root.right = deleteNode (root.right, root.val);
        }
        //node is not leaf, no right child, has left child.
        else
        {
            root.val = predecessor (root);
            root.left = deleteNode (root.left, root.val);
        }
    }
    return root;
}

```

Time Space

## Hashtable / Map / Dictionary

- ADT
- Provides access to data using key.
- key, value pair. (datatype don't have to match)
- Hash function maps keys to int
- In Java, hash fn is Object.hashCode() // (can override)
- Collision - same hash value for <sup>same</sup> diff i/p  
Jane Jones → hash(Jones)  
Mike Jones → hash(Jones)

load factor: how full a hash table is

$$\text{load factor} = \frac{\text{no. of items}}{\text{capacity}} = \frac{\text{size}}{\text{capacity}} = \frac{5}{10} = 0.5$$

used to know when to resize the array backing the hashtable

LF - too low → lot of empty space

- too high → collisions

- can affect time complexity

- \* Linear probing } implement
- \* Chaining } (linklist)

### DPS:

Uses -

- Traverse all vertices in a graph
- Traverse all paths b/w any two vertices in a graph
- $O(V+E)$ . - DPS.
- Space -  $O(V)$
- Ideal DS - Stack

### BFS

- Uses

- Traverse all vertices in a graph
- Find shortest path b/w 2 vertices, all edges have equal & positive weights.

$O(V+E)$  - Time

Space -  $O(V)$

Ideal DS - Queue

## Recursion

Properties -

- 1- A base case - or cases - a terminating scenario that does not use recursion to produce an answer

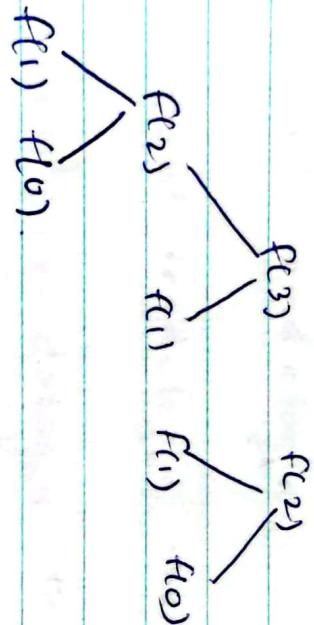

2. A set of rules - or recurrence relation that reduces all other cases towards the base case.

Memoization

- to avoid duplicate calculations we store intermediate results

e.g. Fibonacci series

$f(n)$

public class fibonacci {

HashMap<Integer, Integer> map = new HashMap<>();

```
private int fib(int n)
{
    if(map.containsKey(n))
    {
        return map.get(n);
    }
    else
    {
        int result;
        if(n==2) return n;
        else result= fib(n-1)+fib(n-2);
        map.put(n, result);
        return result;
    }
}
```

## Time complexity.

- Given a recursion algorithm, its time complexity  $O(m)$  is typically the product of number of recursion invocations ( $R$ ) and time complexity of calculation  $O(s)$   
$$O(T) = R * O(s)$$

Tail Recursion - recursive fn call is the final instruction in the recursion fn. And there should be only one recursive call in the function.

- does not require recursion space.

## Divide and conquer.

Recursively breaking the problem down into two or more subproblems until these subproblems become simple enough to be solved directly. Then combine the results of these subproblems to form the final solution

- naturally implemented in the form of recursion.

Divide  $\rightarrow$  conquer  $\rightarrow$  combine

## Master Theorem

$$T(n) = aT\left(\frac{n}{b}\right) + f(n).$$

If  $a > b^d$  i.e.  $d < \log_b a$  then  $T(n) = O(n^{\log_b a})$

If  $a = b^d$  i.e.  $d = \log_b a$  then  $T(n) = O(n^d \log n) = O(n^{\log_b a} \log n)$

If  $a < b^d$  i.e.  $d > \log_b a$ . then  $T(n) = O(n^d)$ .

## Recursion

function that calls itself.

base case - terminating case.

recurrence relation - reduces all other cases towards basecase

eg - string reverse.

- printReverse (char[] str)

{

    helper(0,str);

}

'helper (int index, char[] str)

{

    if (str == null || index >= str.length)

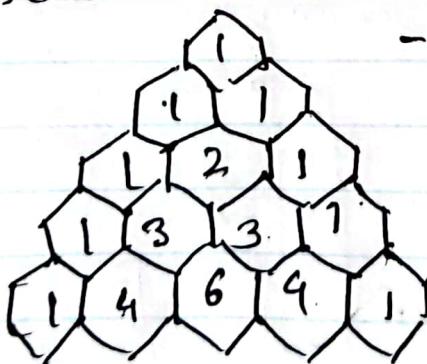

        return;

    helper(index + 1, str);

    System.out.print(str[index]);

}

Pascal's Δ.

- leftmost & rightmost are always 1.

- for rest, each number is sum of two numbers directly above it in previous row.

$$f(i,j) = 1 \text{ where } j=1 \text{ or } i=j. \quad // \text{base case}$$

$$f(i,j) = f(i-1,j-1) + f(i,j-1) + f(i-1,j) \quad // \text{recurrence rel}$$

Fibonacci - 0 1 1 2 3 5, 8, 13, ...

~~Time =~~

Time = no. of recursion iterations  $\times$  complexity of calculation.

$$O(T) = R * O(S)$$

## Dynamic programming

DP - overlapping subproblems.

bottom up tabulation.

Top-down  
memoization

- iteration from base

## Fibonacci

$$F(0) = 0$$

$$f(1) = 1$$

for i = 2 to n -

$$f(i) = f(i-1) + \mu_{i-2}$$

卷之三

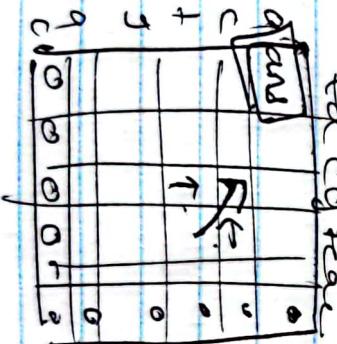

No spread of recursion:

-easy to write

when to use np

— decisions depend on earlier decisions.

longest common subsequence (LCS) of str1, str2).

۲۷۰

`dpc[rows][cols] = max(dpc[rows+1, cols], dpc[rows,`

~~oder~~ return option).

function & Client

If  $i = 0/1$  return  $i$

if it is not in memo

`memo[i] = f(i-1) + f(i-2)`

# Dynamic Programming

2 characteristics

- 1) Overlapping subproblems - smaller version of original problem that are re-used multiple times.
- 2) Optimal substructure - an optimal solution can be formed from optimal solns to the overlapping subproblems of original problem.

2 ways to implement a DP problem

- 1) Bottom up (Tabulation). (Iteration)
- 2) Topdown (memoization)

Starts at base cases.

Eg.

$f = \text{array of len}(n+1)$

$f[0] = 0$

$f[1] = 1$

for  $i = 2$  to  $n$

$f[i] = f[i-1] + f[i-2]$

memo = hashmap

Function  $F(\text{integer } i)$ :

if  $i$  is 0 or 1:

return  $i$

if  $i$  doesn't exist in memo:

$\text{memo}[i] = F(i-1) + F(i-2)$

return  $\text{memo}[i]$ .

Which is better?

- Bottom up run time faster, as iteration does not have overhead that recursion has.
- Top down is easy to write, because with recursion ordering of subproblems don't matter, whereas with tabulation we need to go through logical ordering of subproblems.

When to use DP

- 1) optimum value. (min/max/no. of ways of do something)
- 2) future decisions depend on earlier decisions.

framework for DP problems. (Ref- Climbing stairs).

State → a variable that can sufficiently describe a scenario.

To solve a DP problem we need to combine 3 things -

1. A function or data structure that will compute/contain the answer to the problem for every given state.

e.g:  $dp(i) \rightarrow$  no. of ways to climb the  $i^{th}$  step.

(literally original problem, but generalized for a given state).

2. A recurrence relation to transition between states.

$$dp(i) = dp(i-1) + dp(i-2).$$

- relates diff states with each other.

3. Base cases, so our recurrence relation doesn't go infinitely.

$$dp(1) = 1 \quad dp(2) = 2.$$

- which states can I find ans to without using DP?

class solution?

private int dp(int i) {

A fn that represents ans to the problem  
a given state.

    if(i==2) return i; //Base case

    return dp(i-1) + dp(i-2); //Recurrence reln.

}

~~not adp  
no memoization~~

public int climbStairs(int n)

    return dp(n);

{

str.append(possiblelett)

backtrack(index+1, str)

3. path.deleteCharAt(path.length()-1).

3.

$O(4^n N)$

## 2. Generate Parenthesis

```
generateParen( int n )
{
    list<string> com = new ArrayList<string>();
    generateAll( new char[2*n], 0, &com );
    return com;
}
```

```
generateAll( char cur[], cur, pos, com );
```

```
if ( cur.length == pos )
```

```
{ if ( valid( cur ) )
```

```
    com.add( cur + new String( cur ) );
```

```
}
```

```
else {
```

```
    cur[pos] = '(';
```

```
    generateAll( cur, pos+1, com );
```

```
    cur[pos] = ')';
```

```
    generateAll( cur, pos+1, com );
```

```
}
```

```
valid( cur )
```

```
{ bal = 0
```

```
for ( curr.length )
```

```
    if ('(') bal++
```

```
    else bal--
```

```
if bal = 0 true
```

```
else false
```

0 ( $2^{2n}$ ,  $n$ ) sequences  
valid.

### 3. Word search.

char(3D) board.  
rows, cols.

public bool exist(board, word)

{

for(i > rows

& for(j > cols

{

if(this.backtrack(r, c, word, 0))

return true

}

ret false

backtrack(r, c, word, index)

{

if(index >= word.length) true

if(r < 0, > rows, c < 0, > cols, || this.board[r][c] !=

word.charAt(index))

ret false

(r, c) is somehow good - if it's good

bool ret = false

this.board[r][c] = '#'

if go in 4 directions

if ret break;

this.board[r][c] = word.charAt(index))

return ret;

3.

O(N<sup>3</sup>). O(1)

## Dynamic Programming

1. Coin change (coins[], amount)

Bottom up

Ex:

max = amount + 1;

int[] dp = new int[max];

Arrays.fill(dp, max)

dp[0] = 0

for (coin)

{ for (i=0; i<amount; i++)  
 dp[i] += dp[i - coin]; }

for (i=1 to amount)

for (each coin[j])

if (coin[j] ≤ i)

{

dp[i] = Math.min(dp[i], dp[i - coin[j]] + 1)

}

return dp[amount] > amount ? -1 : dp[amount].

O(s+n) s=amount, n=coins.length

2. word break (str s, wordDict)

Ex:

Set<String> dict = new HashSet<>(WordDict);

boolean dp[s.length+1]

dp[0] = true.

O(n³), O(n)

for (i=0, i < s.length; i++)

{

for (j=0, j < i; j++)

{

if (dp[j] && wordDict.contains(s.substring(j, i)))

dp[i] = true;

break.

3.

longest increasing subsequence.

TC:  $O(n^2)$  SC:  $O(n \cdot \log n)$

Arrays.fill(dp, 1)

```
for (i=1, i<nums.length; i++)
```

```
{
```

```
    for (j=0; j<i; j++)
```

```
{
```

```
        if (nums[i] > nums[j])
```

```
            dp[i] = Math.max(dp[i], dp[j]+1)
```

```
3.
```

return max from dp array.  $O(N^2) \cdot O(1)$ .

Maximum subarray. Cint nums[])

```
int maxsubarray = Integer.MIN_VALUE
```

```
int cursubarray = -u - nums[0]
```

```
for (i=0; i<nums.length; i++)
```

```
{
```

```
    int num = nums[i]
```

```
    cursubarray = Math.max(num, num+cursub)
```

```
    maxsub = -u - (maxsub, cursub)
```

```
3
```

```
return maxsub
```

```
}
```

```
 $O(n), O(1)$ 
```

## Top down

```
HashMap<int, int> memo = new HashMap<>();
```

```
private int dp(int i)
{
    if (i <= 2) return i;
    if (!memo.containsKey(i)) {
        memo.put(i, dp(i-1) + dp(i-2));
    }
    return memo.get(i);
}
```

```
3.
```

```
public int climb(int n)
{
    return dp(n);
}
```

3.

$T = O(n)$ .  $S = O(n)$

## Bottom up

```
public int climbStairs(int n) {
```

```
    if (n == 1) return 1;
```

```
    int[] dp = new int[n+1];
```

```
    dp[0] = 1;
```

```
    dp[1] = 2;
```

```
    for (int i = 2; i < n; i++)
```

```
    {
        dp[i] = dp[i-1] + dp[i-2];
    }
```

```
    return dp[n];
}
```

3.

```

Search -  $O(\log n)$

Ins -  $O(\log n)$

## Comparable & Comparator

Comparable - is an interface defining a strategy of comparing an object with other objects of same type. This is called class's "natural ordering".

In order to sort, you have to declare that object as comparable, and then use `compareTo()` method.

```
public class Player implements Comparable<Player>
```

@Override

```
public int compareTo(Player otherplayer) {
```

```
    return Integer.compare(getRanking(), otherplayer.getRanking());
```

3.

3.

`Integer.compare(x, y)` ⇒ return

-1.       $x < y$   
0           $x = y$

1           $x > y$ .

Comparator - The comparator interface defines a `compare(arg1, arg2)` method with two arguments that represent compared objects, and works similarly to `Comparable.compareTo()` method.

```
public class PlayerAgeComparator implements Comparator<Player>
```

@Override

```
public int compare(Player one, Player two) {
```

```
    return Integer.compare(one.getAge(), two.getAge());
```

3      3

How to use -

- 1) create an instance of comparator
- 2) use in sort.

eg → PlayerAgeComparator pagecamp = new PlayerAgeComparator();  
Collections.sort(footballteam, pagecamp)

### Java 8 Comparators

lambda exp & comparing() static factory method.

eg.

Comparator byRanking = Comparator.comparing(  
(Player player1, Player player2) → Integer.compare(  
player1.getRanking(), player2.getRanking());

The Comparator.comparing() method takes a method calculating property that will be used for comparing items and returns a matching comparator instance.

Comparator<Player> byRanking =  
Comparator.comparing(Player::getRanking);

Comparator vs Comparable

Comparable - good for defining default ordering.

So when to use Comparator?

Sometimes we can't modify source code of the class whose objects we want to sort and can't use Comparable. Comparators allows to avoid adding additional code to our domain classes.

We can define multiple different comparison strategies, which isn't possible using Comparable

Subtraction trick - avoid (Integer Overflow)

Comparator<Player> comp = (p<sub>1</sub>, p<sub>2</sub>) → p<sub>1</sub>.getRank() - p<sub>2</sub>.getRank()

## Concurrency & Threads.

Process: a unit of execution.

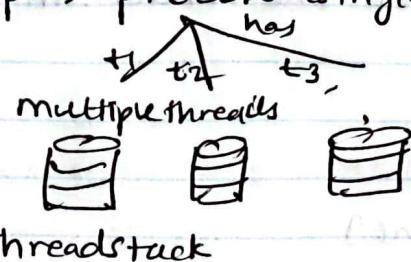

Interchangably called application.

Each java app has its own memory space - HEAP.

Thread: a unit of execution within a process.

- Every process has atleast one thread - main thread
- may have multiple system threads.
- Every thread created by a process shares the process's memory & files\*
- Thread has thread stack.

Java app → process (single)

\* Why multiple threads?

- long running task will run in background, no freezing
- api requires us to provide one.

Concurrency: one task doesn't have to complete before another can start.

### Creation & execution

We can't guarantee the order in which threads will execute.

1) Extend Thread class, override run method.

```
public class Main extends Thread {  
    public void run() {  
        System.out.println("new thread")  
    }  
}
```

### Execution

- create instance.
- call start() method

## What is a thread?

### 1) Runnable interface

```
public class Main implements Runnable {  
    public void run() {  
        System.out.println("Hello");  
    }  
}
```

### How to run -

Pass an instance of class to Thread object's constructor and then call thread's start method.

```
Thread th = new Thread(new Main());  
th.start();
```

- \* We can't guarantee the order in which threads will execute.

Just for fun

```
new Thread() {  
    public void run() {  
    }  
}
```

System.out.println("Hello");

Passed on Thread object as run() method parameter →  
3. start(); something got to run in parallel

Created object of Runnable interface and passed it to Thread object's constructor

Printed out "Hello"

Threads and their thread objects are created separately, so they don't share memory space.

Each thread has its own local variable and its own stack.

So, if we change one variable in one thread, it won't affect other threads.

Example: Print "Hello" 10 times.

Output: Hello 10 times.

```
setName("...xyz");
getName();
sleep(3000); ms./ms, ns.
```

Interrupt: stop a thread from doing what it is doing to do something else

Two checks:

- 1) exception
- 2) periodic checks for interruption.

```
th.interrupt();
```

- \* join() → to terminate another
- \* sleep(3000); it waits for 3000 sec or return.

Threads share heap memory, thread stacks are not shared

- \* Synchronized - only one thread can access at a time  
(don't synchronize on local variables)

Thread safe ⇒ all critical sections are synchronized

```
wait(); - release all locks, wait
notifyAll();
notify().
```

Thread can be suspended in middle unless the operation is atomic.

ArrayList is not threadsafe. - no race conditions.  
Vector is threadsafe.

Multithreading - multiple threads of execution inside the same application.

Concurrency problem: Bcoz threads run at same time as other parts of program, there is no way in which order the code will run. When the threads and main program are reading & writing same var, the values are unpredictable. The problem that result from this are concurrency problem.

stop a thread. → Thread.stop()

Critical section → section of code that is executed by multiple threads where the sequence of execution of the threads makes a difference in the result of concurrent execution of critical section.

Race condition → is a concurrency problem that may occur.

critical section

- 1) Read-modify-write
- 2) check-then-act (e.g. - map - check & remove)

Preventing race conditions -

- 1) ensure critical section is executed as an atomic code (synchronized block of Java code)
- 2) use locks, etc.

Synchronized blocks - thread safe

- can only be executed by a single thread at a time, thus avoid race condition.

limitation - allows only one thread at a time.

what if 2 threads only want to read? we can allow.

Thread signalling

wait()

notify()

notifyAll()

Deadlock -  $a \rightarrow b \rightarrow c$ .

Prevention

- 1) lock ordering  $\rightarrow$  make sure all locks are always taken in the same order by any thread.
- 2) lock timeout
- 3) deadlock detection.  
check if it has any locks required for other thread that is waiting for

Locks - thread synchronization mechanism.

lock. lock = new Lock()

lock.lock();      lock.unlock();

Semaphore  $\rightarrow$  thread synchronization construct that can be used either to send signals b/w threads to avoid missed signals or to guard critical section like you would with a lock.  
take()  $\approx$  notify()  
release  $\rightarrow$  wait()  
signal.

Threading

## Java Comparator

```
class NodeComparator implements Comparator<ListNode>
{
    public int compare(ListNode k1, ListNode k2)
    {
        if(k1.val > k2.val)
            return 1;
        else if(k1.val < k2.val)
            return -1;
        return 0;
    }
}
```

if doesn't work

use

return Integer.compare(a,b)

```
PriorityQueue<ListNode> q = new PriorityQueue<ListNode>(new NodeComparator());
```

Collections.reverse(list) — list reverse

Collections.reverseOrder() — reverse order

```
PriorityQueue<Integer> pq = new PriorityQueue<Integer>(Collections.reverseOrder());
```

char c.

$c - 'a'$  = 0. if  $c \geq a$

$c - 'a'$  = 1. if  $c \geq b$

2d array len.

{60, 15, 9, 10},

{1, 2, 3, 4, 5}

{1, 2}

arr[0].length = 4

arr[1].length = 5

arr[2].length = 2.

Arrays.copyOf(points, k) → return k elements from points array

Arrays.sort(points, (a, b) → squared(a) - squared(b));

Comparable & Comparator.

java.util.Arrays.sort(arr); ⌈ order ⌉  
for  $\forall i \rightarrow$  Collections.reverse(arr); after sorting

For object array. (Eg-employee)

public class Employee implements Comparable<Employee> {

@Override

public int compareTo(Employee employee)

return (this.salary - employee.salary)

}

compareTo. ↗ returns  $\{<, =, >\}$

$obj_1 > obj_2$  if  $x > 0$

$obj_1 < obj_2$  if  $x < 0$

$obj_1 = obj_2$  if  $x = 0$ .

\* Arrays.sort(employees, new Comparator<Employee>())

{@Override}

public int compare(Employee e1, e2)

?

return  $e1.salary > e2.salary$

3

};

\* [0, 2], [3, 4], [1, 2]

Arrays.sort(intervals, (a, b)  $\rightarrow$  Integer.compare(a[0], b[0]));

Lambda functions - do not need name, can be implemented right in body of method  
parameter (optional), arrow token, body.

$(a, b) \rightarrow \text{Integer.compare}(a[0], b[0])$

parameter  $\rightarrow$  expression

$(p_1, p_2) \rightarrow \underline{\underline{n}}$

Arrays.copyOf (input, 0, k)  
 $\underline{\underline{n}} (input, k, input.length)$

JDK - contains JRE, JVM, compiler, Java app launcher, Appletviewer etc.

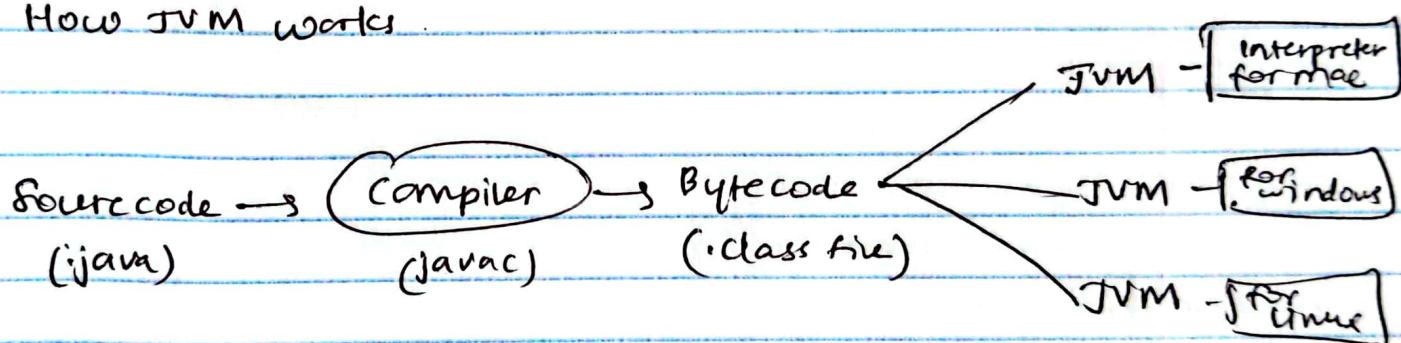

JRE - env on which jvm runs.

- contains JVM, class libraries, compiler, debugger.

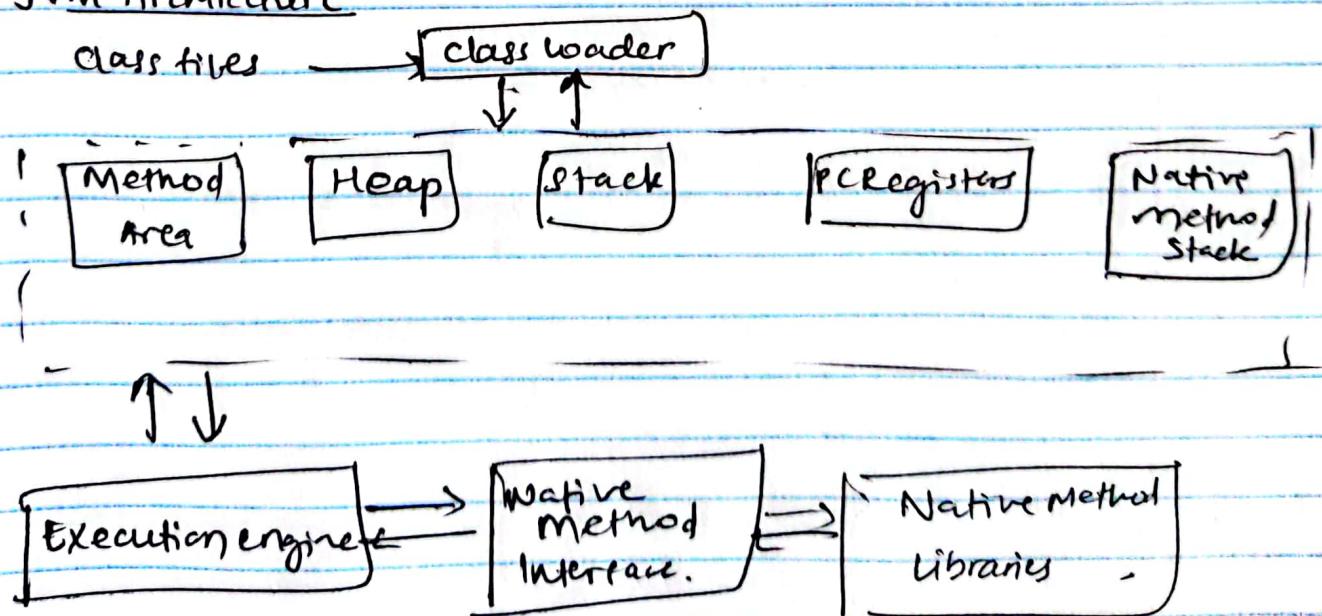

JVM - makes java platform independent.

- it's a virtual machine residing in your real machine and machine lang for JVM is bytecode.
- makes it easy for compiler as it has to generate bytecode for JVM rather than diff machine code for each machine

How JVM works

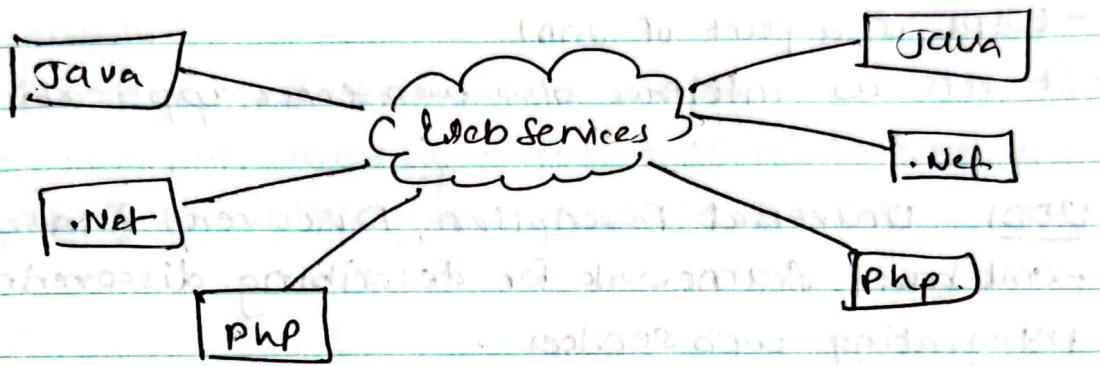

JVM Architecture

## Web Services

### WebService -

- a client server application or application component for communication.
- the method of communication b/w two devices over a network.
- provides a common platform for various applications written in diff. languages to communicate with each other over network.

### Types

- 1) REST
- 2) SOAP.

### features

- XML based
- loosely coupled
- Coarse grained
- Ability to be synchronous or asynchronous
- support RPC
- support Document exchange

### WebService components

- 1) SOAP
- 2) WSDL
- 3) UDDI

SOAP - Simple Object Access Protocol.

- XML based protocol for accessing web services .

- W3C recommendation for communication b/w apps .

- platform & language independent .

WSDL - Web Services Description Language .

- XML doc containing info about web services such as method name, method parameter and how to access it .

- WSDL is a part of UDDI

- It acts as interface b/w web service applications .

UDDI - Universal Description, Discovery & Integration.

- XML based framework for describing, discovering and integrating web services .

- is a directory of web service interfaces described by WSDL, containing info about web services .

SOAP

- is a protocol

- can't use REST as its a protocol

- uses services interfaces to expose the business logic

- standards to be strictly followed

- requires more bandwidth & resource .

- less preferred

- permits XML data format only

REST .

is an architectural style .

- REST can use SOAP because it's a concept & can use any protocol like HTTP, SOAP .

- uses URL to expose business logic

- REST does not define much standards like SOAP .

- less bandwidth & resource .

- more preferred

- allows XML, HTML, JSON etc .

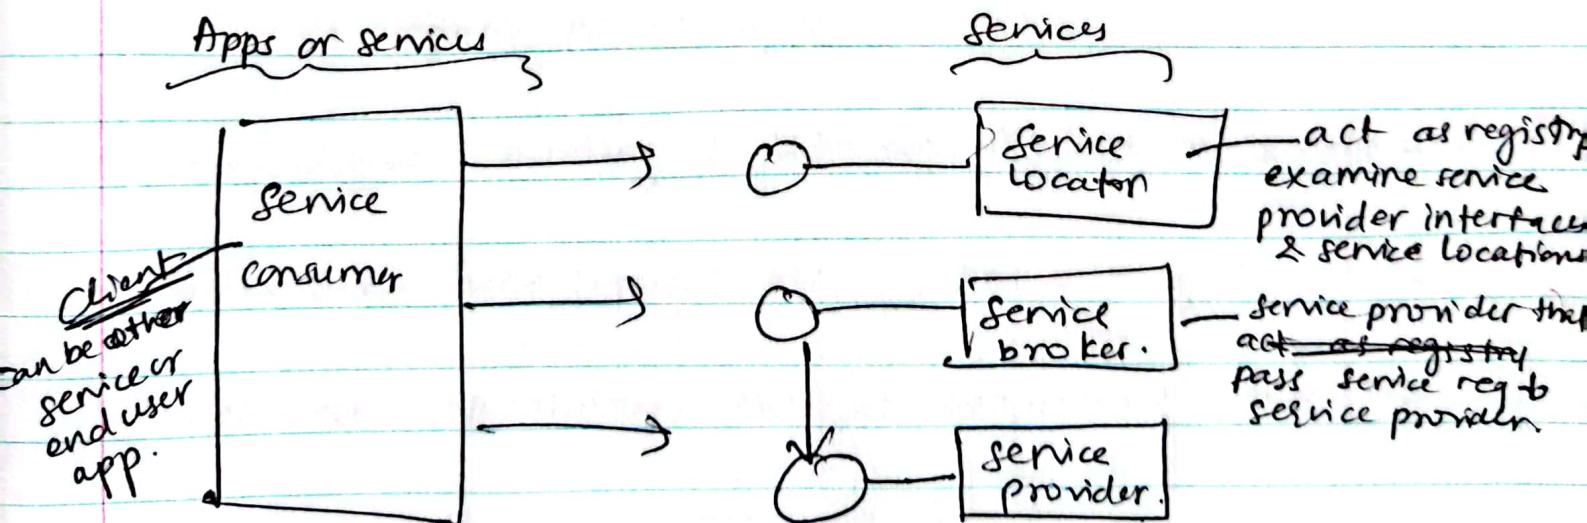

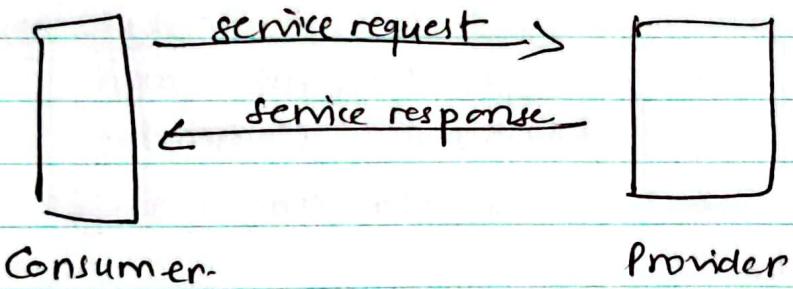

## Service Oriented Architecture (SOA)

- is a design pattern which is designed to build distributed systems that deliver services to other applications through the protocol.
- is a concept only and not limited to any PL or platform.

### Service

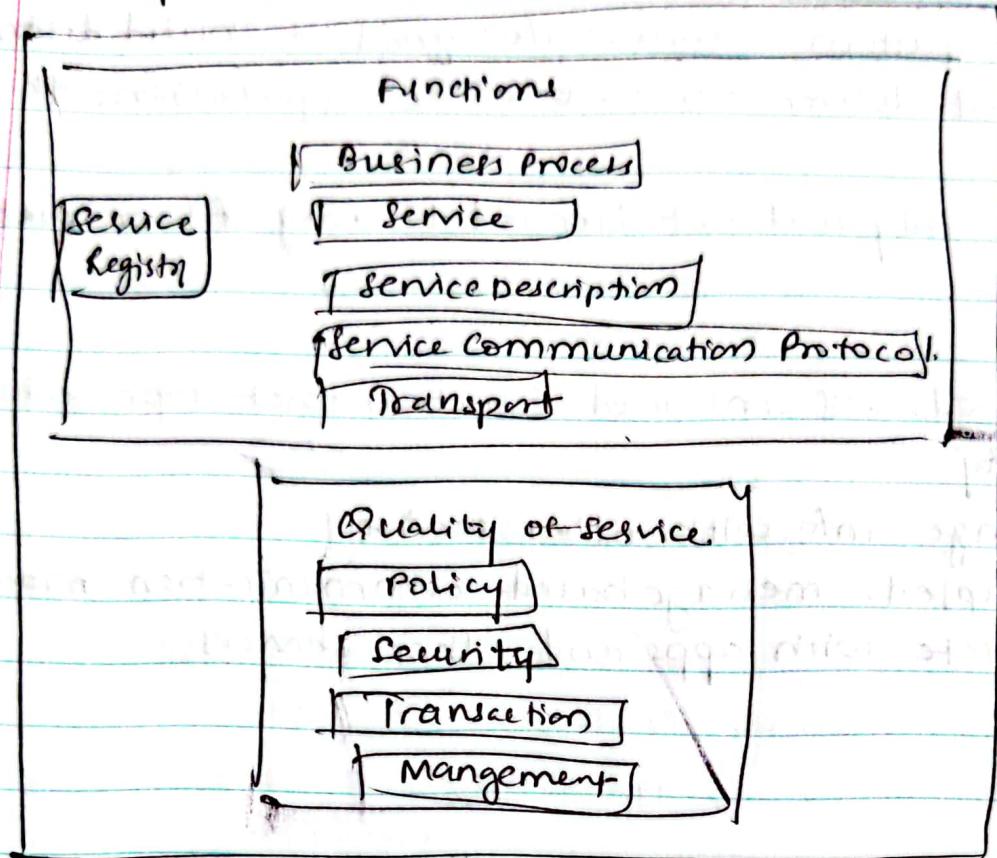

- a well defined, self contained function that represents a unit of functionality
- can exchange info with other service.
- loosely coupled, message based communication model to communicate with apps and other services.

### SOA

Service provider - software entity that implements a service specification.

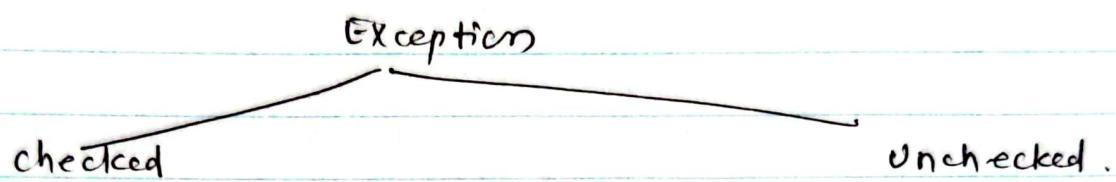

## Components of SOA

## Java Exceptions

Exception: problem in normal flow of execution. If the exception cannot be handled, then the execution gets terminated before it completes the task.

Exceptions are subclass of `java.lang.Exception`.

- checked  
are checked by compiler at the time of compilation.
  - classes that extend `Throwable` class except `RuntimeError` are called checked exception .
  - must either declare exception using `throws` or `try/catch`-
    - eg - `ClassNotFoundException`

- unchecked .  
not checked by compiler.  
The compiler doesn't force to handle this exceptions
  - eg- `ArithmeticException`  
`ArrayIndexOutOfBoundsException` .

`try` - put risky code here.  
`catch` - catches exceptions .  
`finally` - executed everytime , cleanup codes .

### Exception propagation

- first thrown from method which is at top of stack, then if it doesn't catch it pops up method and moves to previous method and so on until caught .

`Thread.join()` → join one thread with end of currently running thread

heights[]

int arr[] = heights.clone(); → copies heights into arr / clone

nums[]

Collections.min(nums) // min of array

Collections.max(nums) // max of array

System.arraycopy (from, indexFrom, to, indexTo, no. of elements)

Arrays.asList(s.split("\\s+"));

Collections.reverse(tit);

Pair - javafx.util.

Pair<Integer, String> pair = new Pair<>(1, "One");

Integer key = pair.getKey()

String val = pair.getValue()

set1.retainAll(set2) → intersection of sets

\* String arr[] = new String[list.size()];  
list.toArray(arr)

map.getOrDefault(a+b, 0) + 1);

Queues<Integers> q = new PQ<<((n1, n2) ⇒ count.get(n1) - count.get(n2))>>

Map.keySet()

Arrays.sort(intervals, (a, b) ⇒ (a[0] - b[0]));

PQ<int> pq = new PQ<<((a, b) ⇒ (a[1] - b[1]))>>;

set1.retainAll(set2)

```
Arrays.sort(logs, new Comparator<int[]>() {
```

@Override

```
    public int compare(int[] log1, int[] log2) {
```

```
        Integer tsp1 = new Integer(log1[0])
```

—u tsp2 — — — (log2[0]);

```
        return tsp1.compareTo(tsp2);
```

3.

});

\* enum Color {GRAY, BLACK}

use → return state.Color = Color.GRAY

hashmap

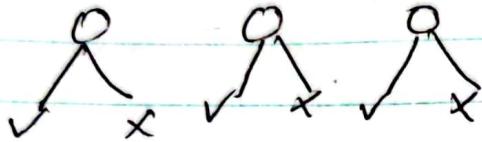

this.map.forEach((key, value) → Collections.sort(value));

DP - Identify -

- 1) Recursion - Enhanced Recursion, overlapping,
- 2) optimal substructure

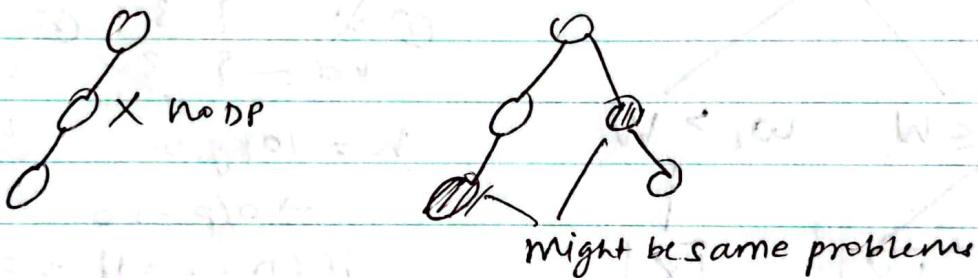

Recursion / DP.
